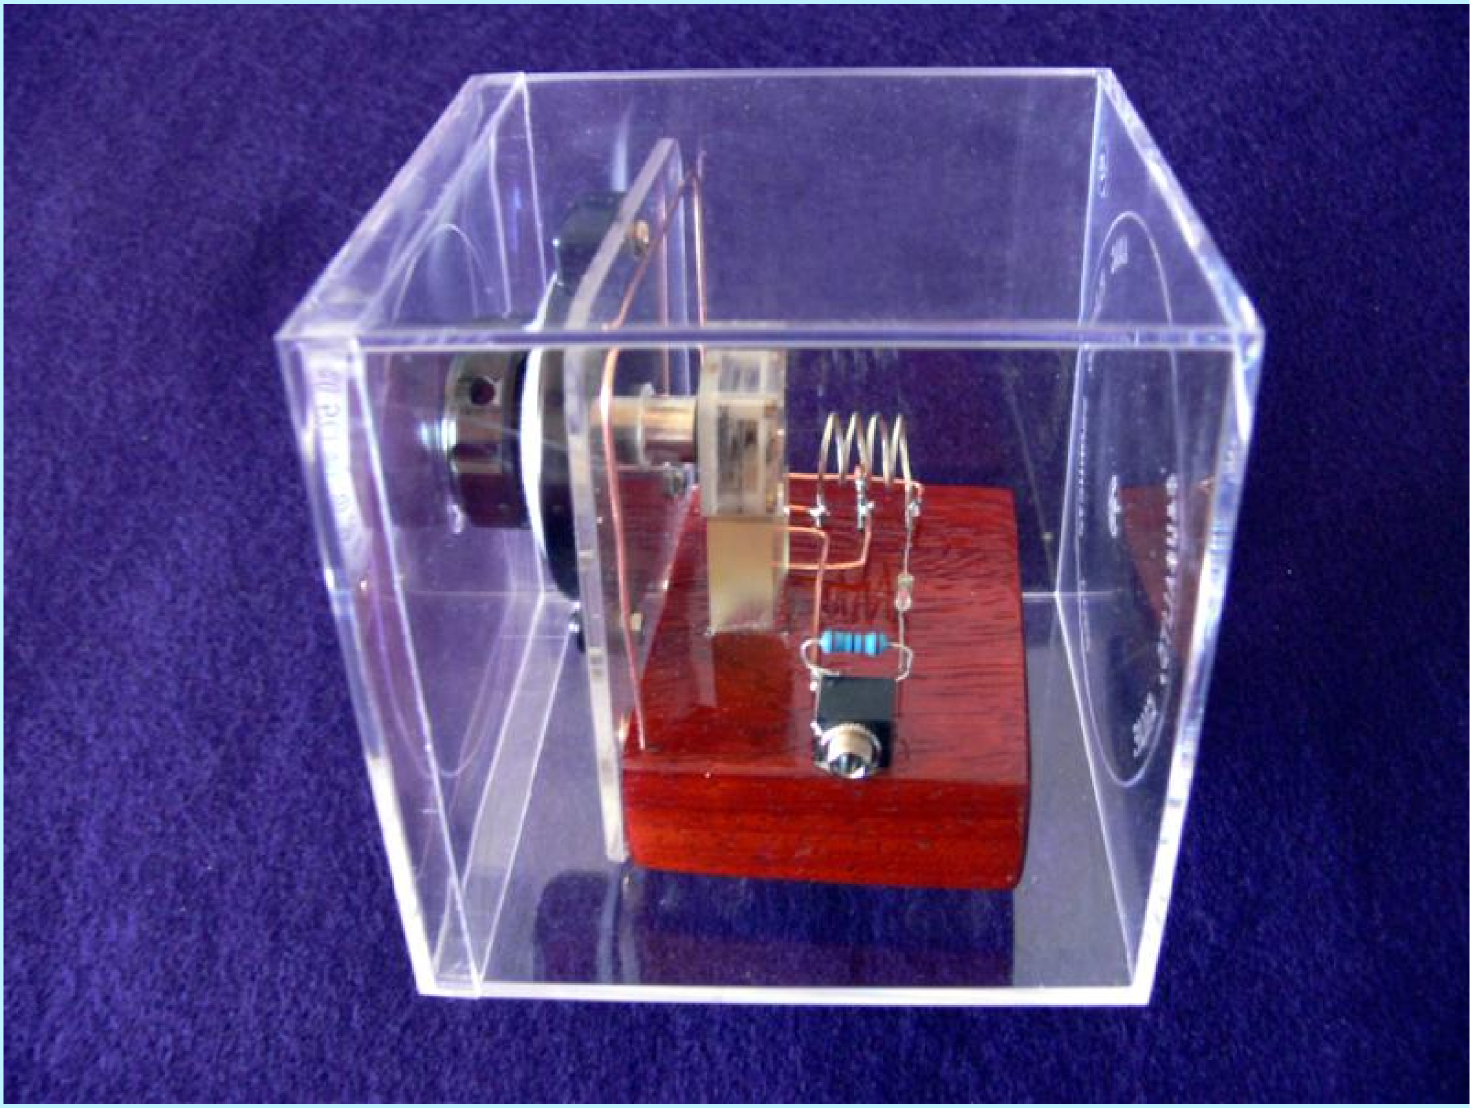
FM Crystal Radios?

copyright © 2006 by Larry J Solomon

I have heard, even from a physicist, that it is impossible to build FM crystal radios. On the other hand some experimenters claim that they have built them. This argument intrigued me to try and build an FM crystal radio, which I have done successfully. To my surprise, the result is an astounding performer, pulling in four local stations in Tucson. When connected as a receiver to a good sound system the sound fidelity is as good or better than more expensive AM radios. In fact, it sounds "high-fidelity".



This picture shows the Solomon FM Crystal Set in an acrylic display case. I made the set specifically to fit inside this case (the case came first).

My definition of a crystal radio is one that is not powered, except by the radio transmission itself and employs a crystal detector. So, it should work without any batteries or AC power. An FM crystal receiver must be able to detect and receive FM signals well enough to be heard in earphones without any such extra power.

This FM receiver is an amazing performer. It has crystal clear reception (pun intended), good sensitivity, but only fair selectivity. This set was a discovery for me. I started out by designing and building the normal AM sets. Then one day while testing the "Mystery" set (see my other web links), to my surprise, in addition to the expected panoply of AM stations, I heard a very faint signal that I could not tune out. At first, it seemed too weak to identify. When I tuned out all the AM stations, I was astonished to hear the announcement "KiiM FM, 99.5"! This is a

country music FM station here in Tucson. It was all over the dial, untunable, but the much louder AM signals masked it when they were tuned in.

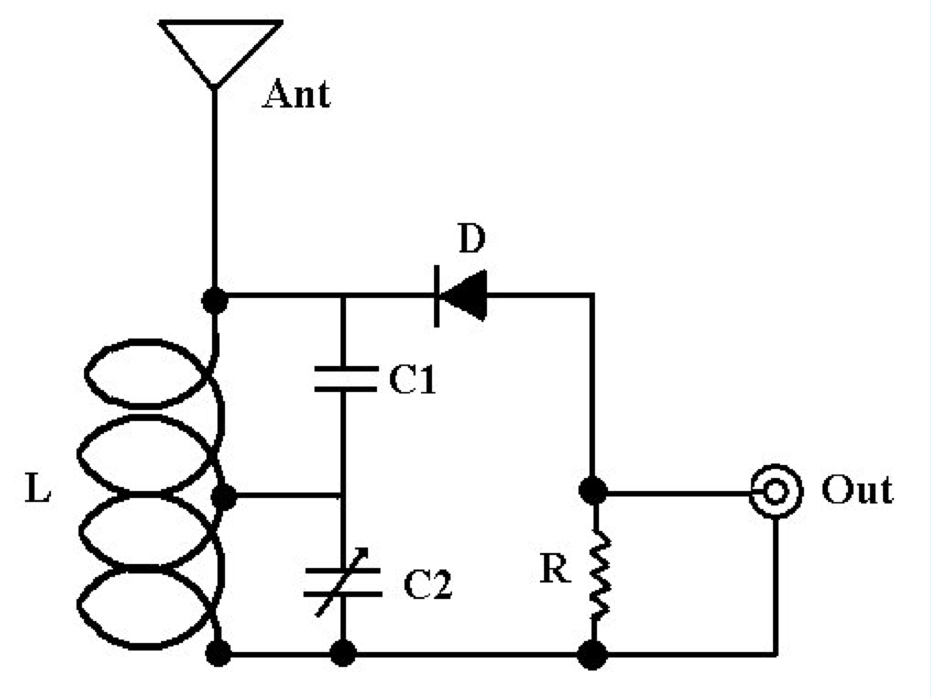
I set myself the task of trying to improve the FM reception. I tried some simple circuit modifications that did not seem to improve anything. Then I connected a dipole antenna instead of the AM antenna I normally use. Suddenly, the FM signal was much clearer, although still weak. By using the audio output and sound system amplifier, I was even more amazed that four different FM stations came in loud (or rather medium) and clear. I found that changing the telescoping antenna length and position I could tune the stations in and out. They were KRQ, KLPX, KiiM, and KHYT all local FM stations with transmitters nearby. Their reception was also affected by the length and position of the audio output cable.

After doing some research, I discovered that there was a physical theory that claimed that FM reception was possible and even probable using the same circuit as an AM receiver. The theory is called "slope detection". So, I set out to find circuit improvements. A web search yielded little, mostly theory. But there was enough information that I thought I could make some modifications to the AM circuits to make them more tunable to FM signals and less tunable to AM. Since FM operates at higher frequencies, all I had to do, I thought, was make the coil and caps smaller. After much "tinkering" I arrived at the current circuit.

The circuit looks identical to a classic AM crystal circuit but is even simpler to build. The components were reduced in dimension to resonate at higher frequencies. This was done by experimenting with smaller and smaller coils and capacitors. The antenna is also much reduced in size (from that of AM) to resonate at higher frequencies (the antenna is crucial). The air variable capacitor I used has two trimmers in it which should be adjusted for best reception.I have found that a commonly available vernier dial and knob will fit the capacitor nicely. See end of article for a picture of the variable. C3 is a ceramic capacitor of 18 pf, but may be anywhere from 10 to 50pf. A detected FM signal is converted to AM due to an effect called slope detection that modulates amplitude.

This FM Crystal Set works best near the transmitter (I have not tested it beyond about 10 miles). Secondly, the sound level is quiet, especially without an amplifier. A quiet room is needed for listening with earphones. One must be willing to move the set around to find a location for the best reception of signals. However, in addition to listening with high impedance earphones (crystal or otherwise), the set can be connected directly to an audio amplifier's low level magnetic input which can then play amplified through a sound system at any volume -- sounds GREAT. In fact, I recommend starting tests with the FM crystal set by connecting it to the low-level phono inputs of a receiver or preamplifier. (Nowadays, many receivers don't even have a phono input!) That way you can crank up the volume, which makes it more likely to find the FM stations. If no signals are detected, I also recommend connecting an external "rabbit ear" antenna or hanging a short wire (12 inches or so) in various positions next to the internal antenna. The variable length of rabbitt ears can help to tune in stations.

No additional wiring or antenna is necessary (the antenna is optimized in length for FM.)

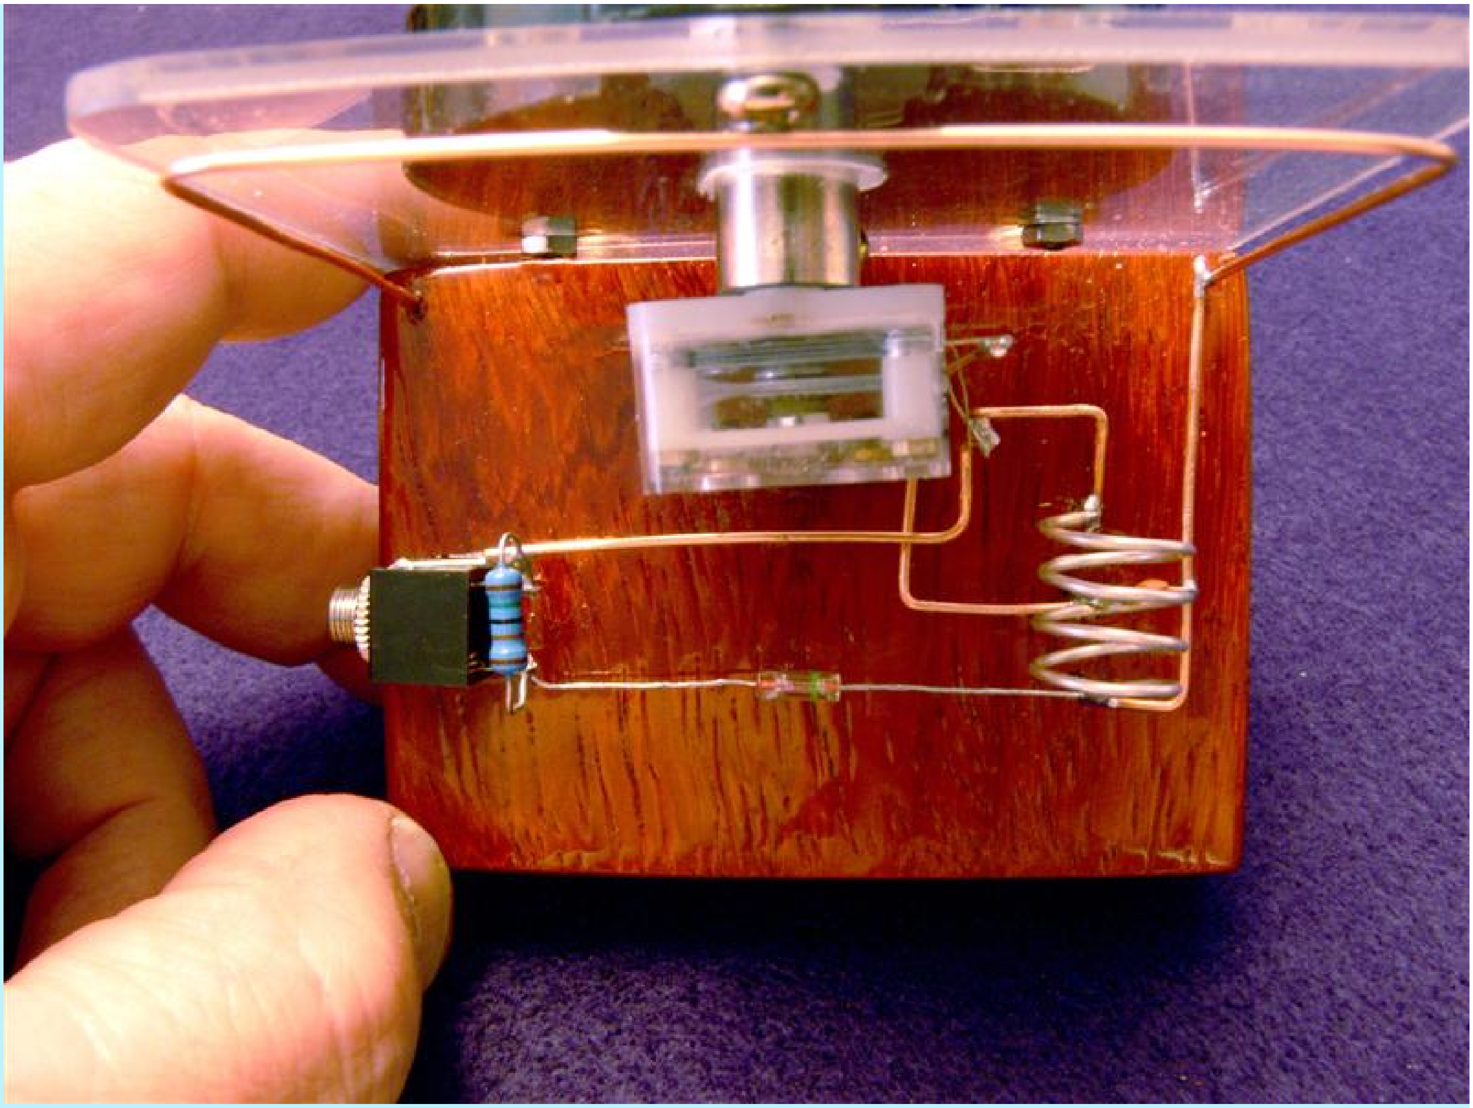


L - 4 turns #18 copper or silver wire, 12mm inside diameter, tapped at 2.5 turns
Ant - 7 inches of #18 bare copper wire
C1 - 18 pf ceramic capacitor
C2 - 50 pf air variable capacitor
D - 1N34 diode or rock crystal
R - 150K resistor

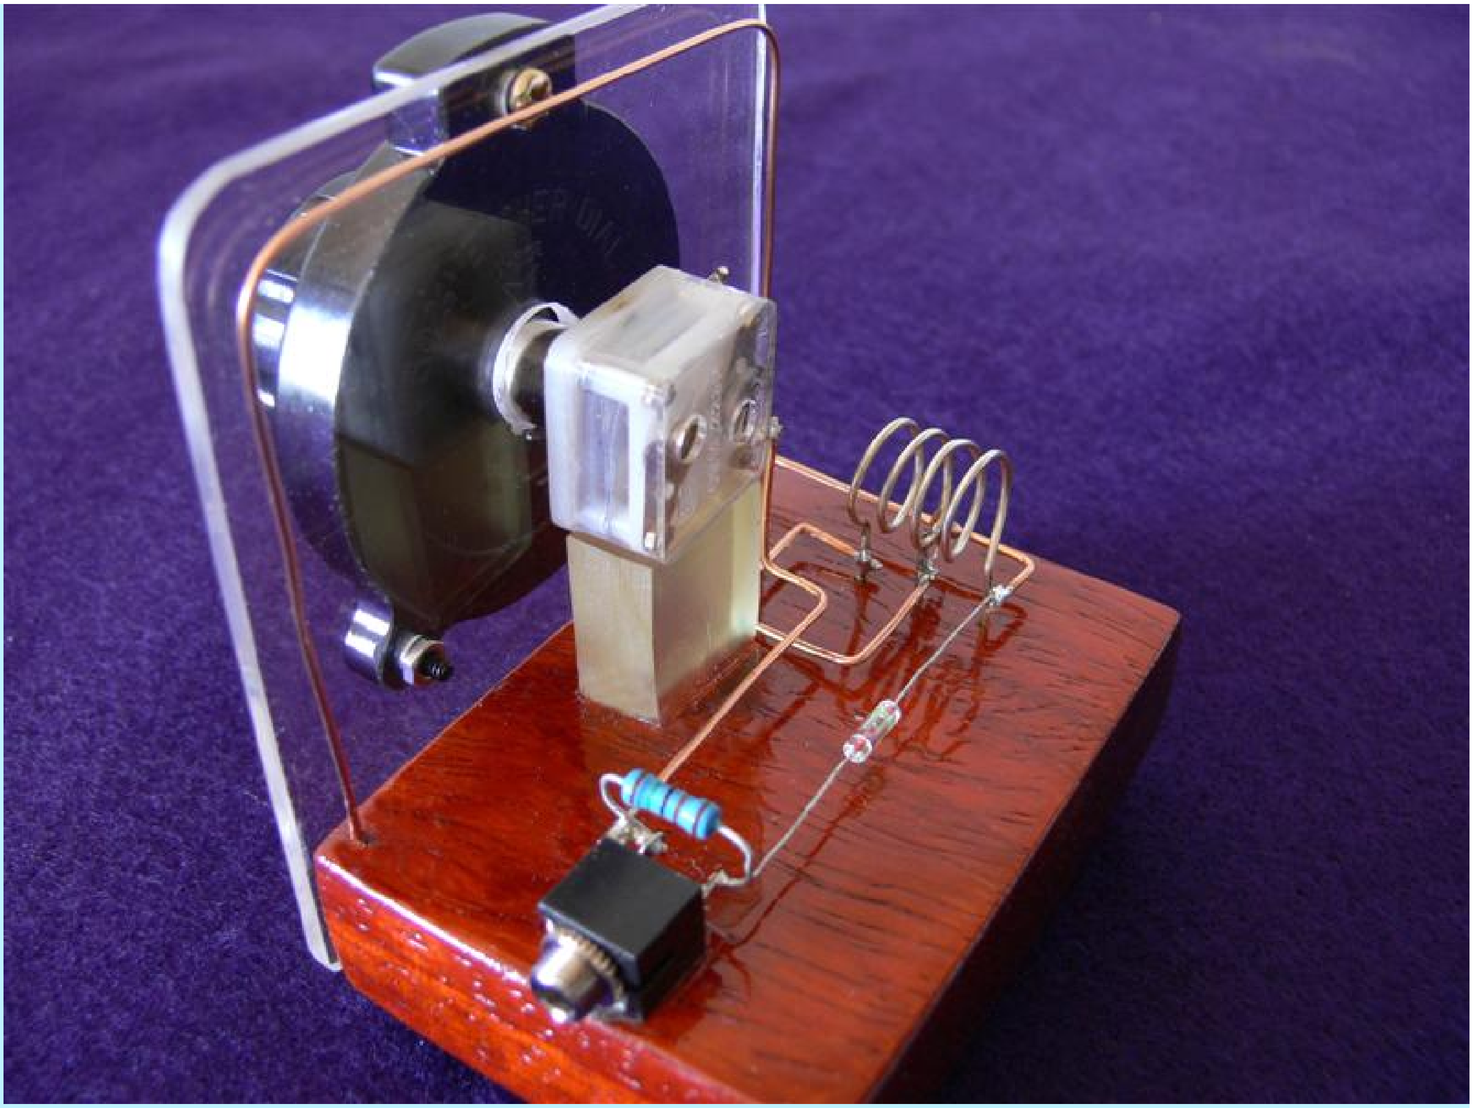
The diode is tapped directly to the antenna. The vernier dial fits directly on the tuning capacitor. The antenna parallels the perimeter of the acrylic face plate. "Military style" #18 AWG wiring is used without any insulation. It is important to keep the components physically close together. The component specifications are the same as in circuit #2. The coil is silver rather than copper, but copper does just as well. I think that the contrast of the silver and copper is beautiful. The coil was wrapped around a Sharpie Permanent Marker, then slipped off and expanded slightly. The wooden base is made from lacquered, polyurethane padouk.

I consider this set a work of art as well as science and think it is the most elegant crystal receiver I have created. I love the contrast of the silver coil, the copper antenna, the clear acrylic faceplate, the black vernier dial, the white and transparent variable capacitor, and the subtle colorings on the resistor, the diode, and the lucite base. Yet the circuit is so ridiculously simple that some will not believe it is possible without building it themselves. No shielding is necessary, and there is no problem with hand capacitance. However, the output cable position may affect reception sensitivity.

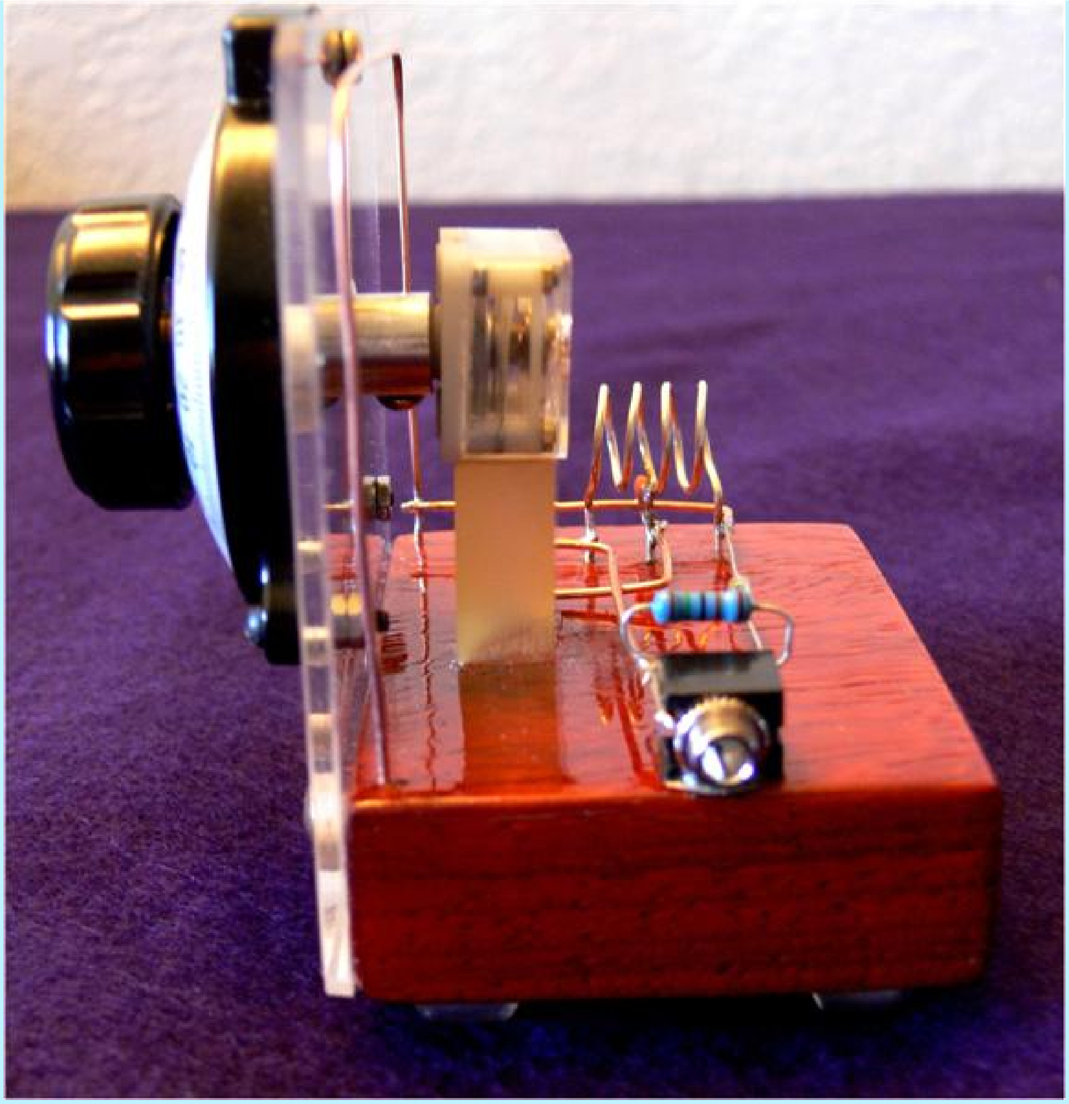
Photos of wired circuit



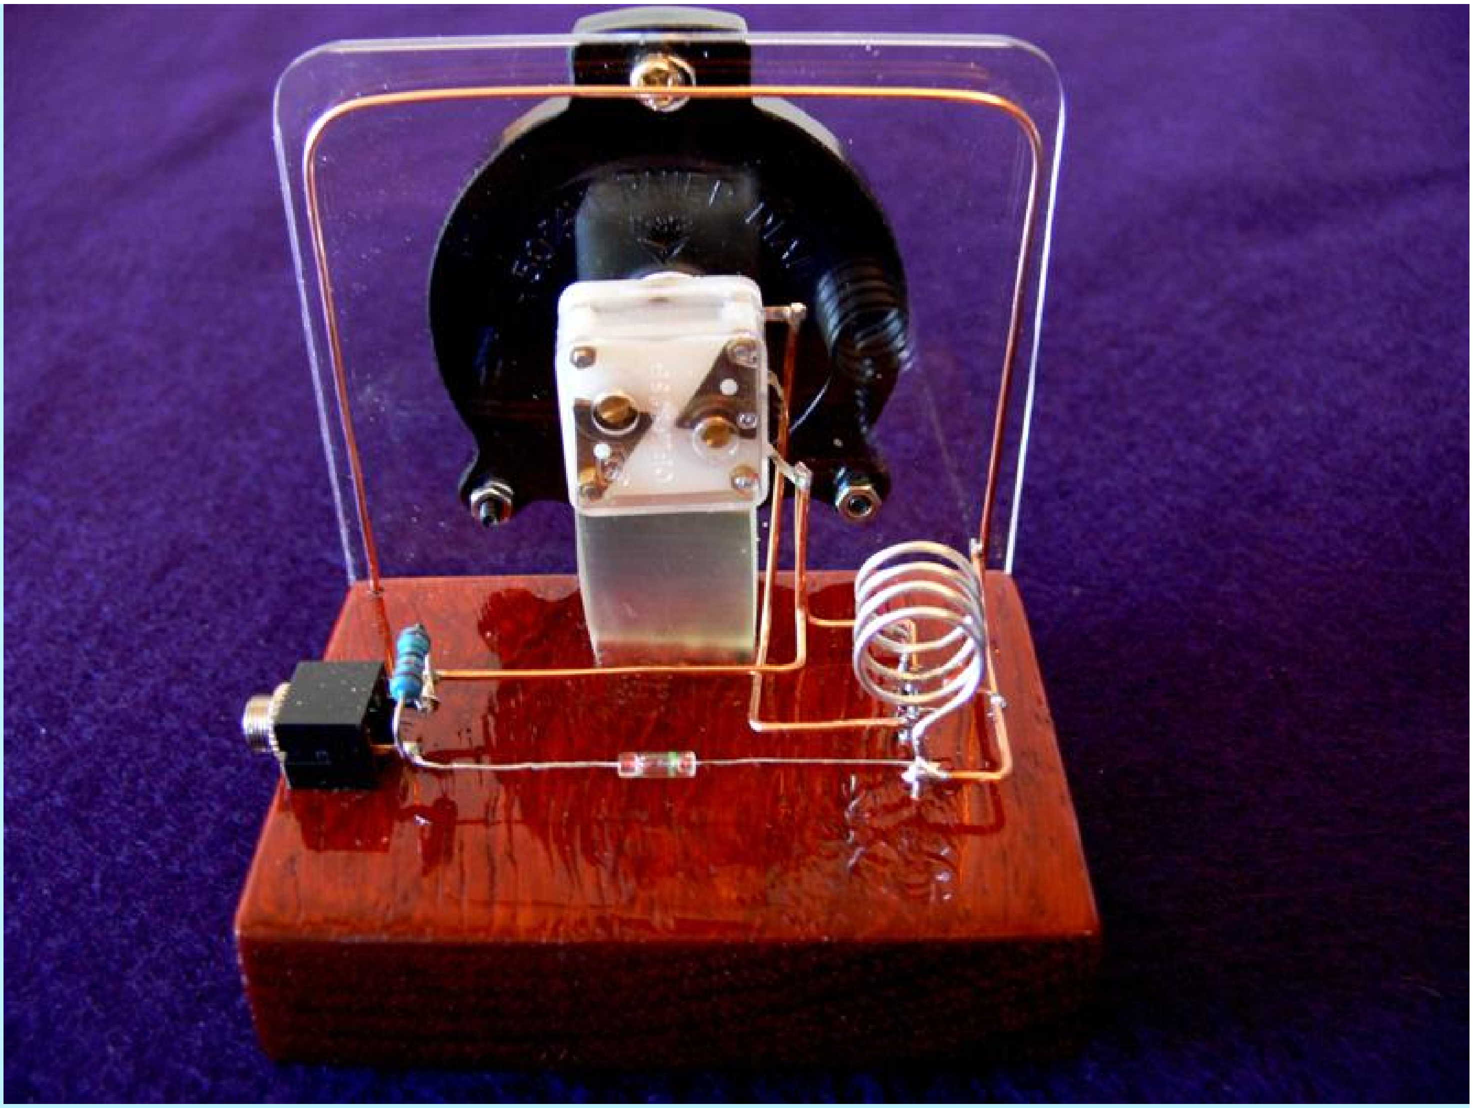
A hand is included in this photograph to show scale. Note the military style wiring, diode, and antenna. I wanted the wiring to create a modern design similar to a Mondrian painting. Not only is this set beautiful, it works! No power and no long antenna! It looks like a work of fiction.



Is this thing imaginary -- science fiction? Well, imagination did play a part, but it is definitely not science fiction. This shot shows the elegance of the FM set best, I think. There is only one resistor and one fixed capacitor.



The inside of the tuning capacitor and the phono jack/output can be seen here. Can you spot the fixed ceramic capacitor? Note the polished edge of the face plate and the reflection in the wooden base.



A quarter-inch piece of lucite was fitted under the tuning capacitor to anchor it. Note the two tiny trimmers on the back of the tuning capacitor. Brass screws were used to enhance appearance.

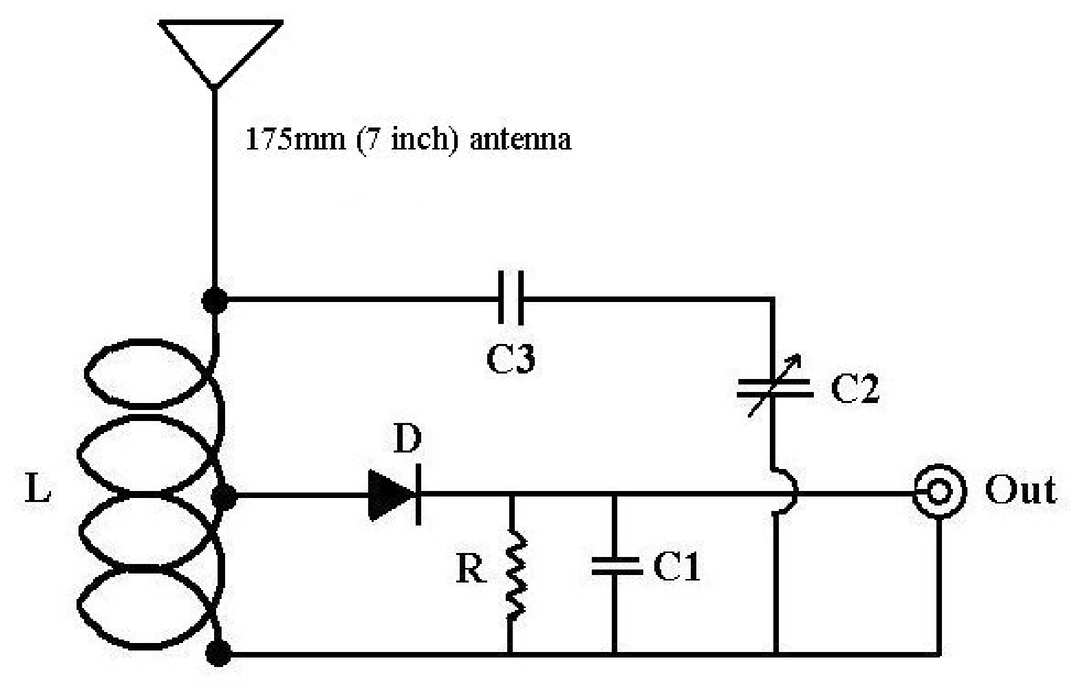
0

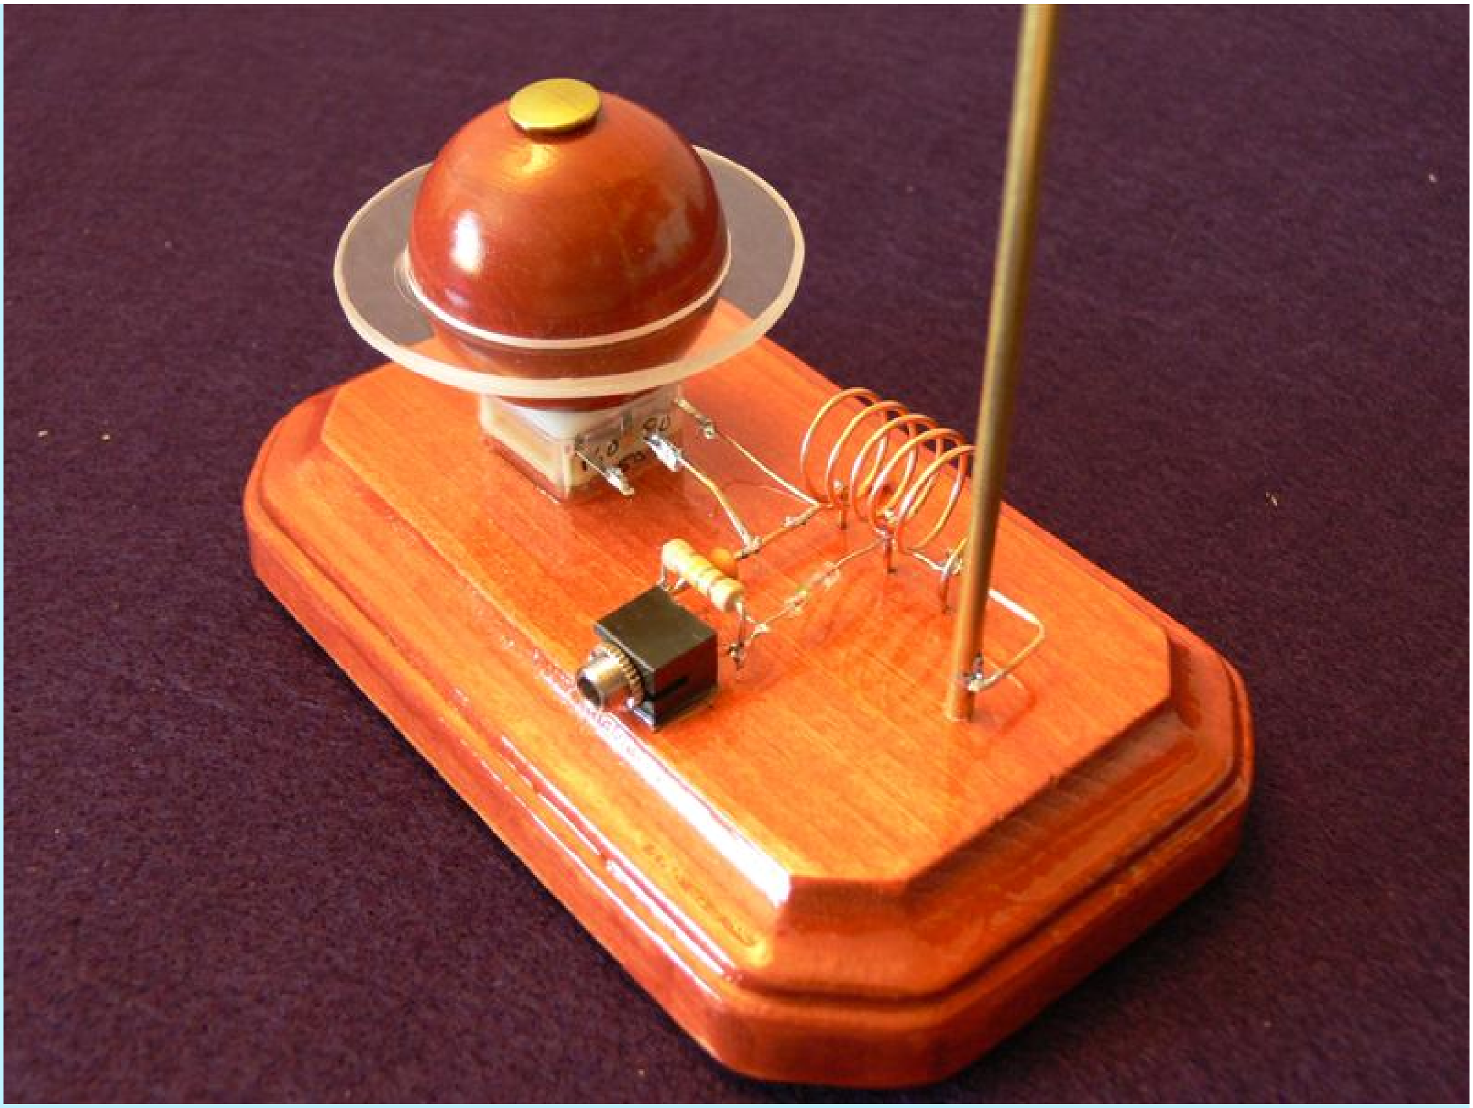
The vernier dial is large to accomodate ease of tuning, and the vernier makes it easy to separate stations. Two golden (brass) wood screws fix the face plate to the base. Holes for the face plate were made with special plastic drills, but ordinary drills may be used if drilled very SLOWLY. The knob is removable.

FM Crystal Circuit #2

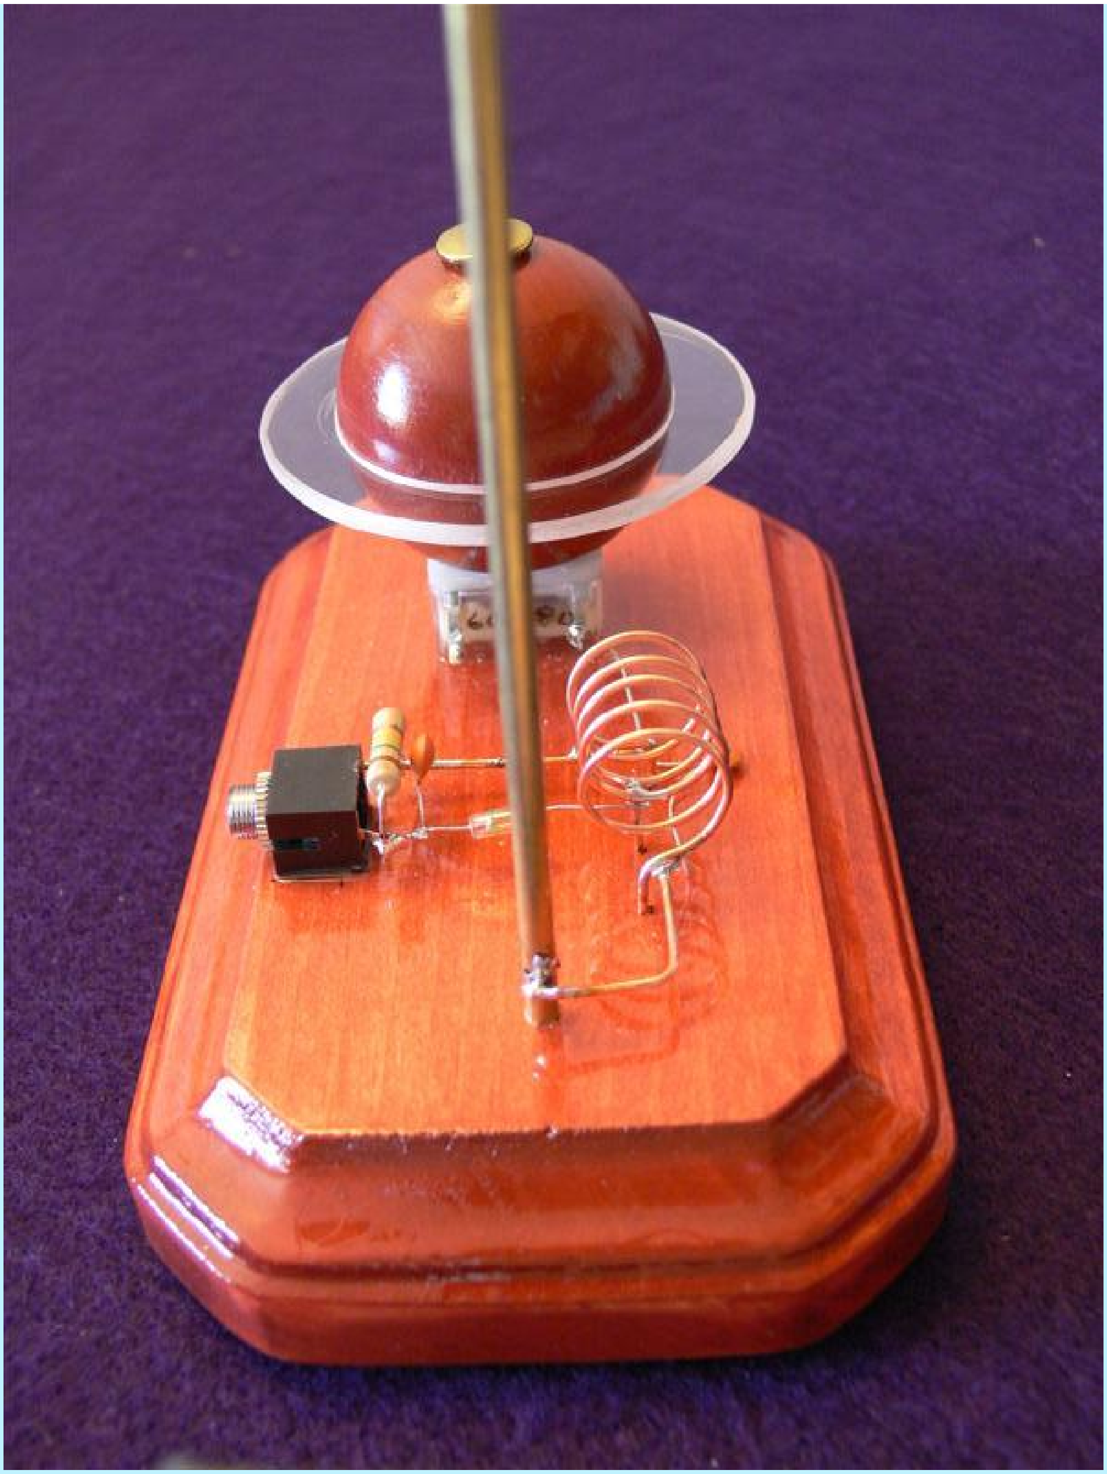


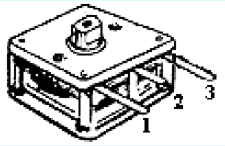
L - 5 turns AWG#18 bare copper or silver wire, 12mm inside diameter, tapped at 2.5 turns
D - 1N34 or rock crystal diode
C1 - 82 pf capacitor
C2 - 80 pf air variable capacitor
C3 - 18 pf capacitor
R - 150K resistor

The following photographs show the circuit wired with the handmade Saturn Dial. and knob. It is perhaps not as visually striking as set No. 1, but it works just as well. In fact, this set was the original version. Notice that all the wiring and coil are copper.



The Saturn dial and knob were fashioned from a "doll's head" from Michael's Arts and Crafts, a piece of lucite cut with two circle cutters, and a brass paper fastener. The knob is fixed to the tuning capacitor with a small machine screw that fits in the hole below the brass fastener. The most difficult part of this was fashioning "Saturn's rings". This must be done very carefully and slowly. The inside edge should be cut slightly undersized and then sanded with a drum sander to fit snugly. The outside edges can be sanded with fine sandpaper and polished with a plastic polisher.





The air variable capacitor may be obtained from Electronix Express at http://www.elexp.com/. Part number 14VCRF10-280P. The 80 pf side is recommended for the second circuit, contacts 2-3. Contacts 1 and 3 were used for the first circuit (50pf).

- OSC: 5-59 pf
- ANT: 5-142 pf
- OSC and ANT Trimmer 10pf range

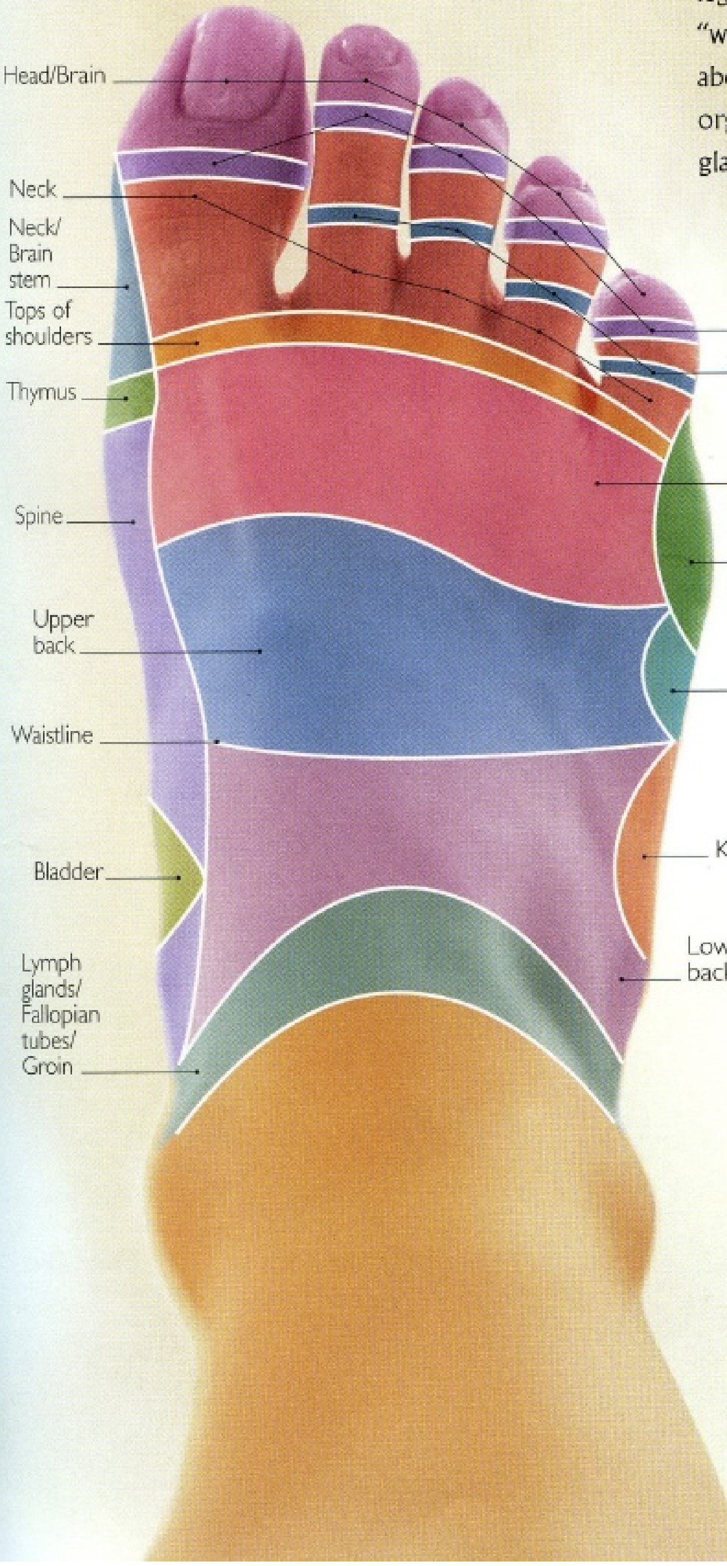
Top of right foot

On the top of the right foot are reflex areas relating to the right side of the body, such as the right arm and leg. A point halfway down each foot is known as the "waistline". The upper back and its organs are mapped above this point, and the lower back and the internal organs it encases are below this guideline. The lymph glands and the groin reflex areas wrap around the ankle.



Head/Brain

Lung/Chest/Breast/Upper back
Arm
Elbow
Knee/Leg
Lower back

Outside foot

The reflex area for the top of the shoulders runs across the toes, with the areas corresponding to the arm and elbow at the side of the foot. The reflex areas for the reproductive organs and for the sciatic nerve and hip, which curve round the ankle bone, can be clearly seen in this view.

According to **Prof. K. Meyl** out of the book **"Scalarwaves"**

Explanation of the longitudinal Wave

and the functional principle of this exhibit

The special properties of the longitudinal wave (scalar wave) have been discovered over 100 years ago by Nicola Tesla. Through the different behaviour, compared to the Hertzian wave (radio wave), there resulted in a scientific dispute. (Similar to the war of currents a couple of years before).
Tesla's experiment, the Wardenclyff-Tower, and the patent drawings that describe the wireless power transmission.

528 Hz

528 Hertz is a frequency that is central to the "musical mathematical matrix of creation."
This is the Love Frequency.
528 is known as the 'Miracle' tone which brings remarkable and extraordinary changes.

The "**Mi**" tone is characterized as an extraordinary occurrence that surpasses all known human powers or natural forces and is ascribed to a divine or supernatural cause. Every day more and more people tune themselves to the harmonic vibrations of 528 Hz music. In addition, the 528 Hz tone alone is scientifically associated with DNA repair.

RECEIVERS FOR BEGINNERS . . .

local broadcasting stations in dual-type headsets with an impedance of 2000 ohms, or higher. The antenna should be a high, well-insulated outdoor type at least 100 feet long, although antennas as short as 40 feet will work. The ground should be made to a cold-water pipe.

The practical receiving range of any crystal receiver is limited to about 40 miles for powerful broadcasting stations. Set No. 2 is double-tuned for improved selectivity. Two coils like the one used in set No. 1 are employed and each coil is tuned by one section of a dual variable condenser. Coupling between the two tuned circuits is by means of a "gimmick" made by twisting two pieces of insulated wire together for a length of about 4 in. This is condenser C3. The longer this "gimmick" the louder the signals, but the poorer the selectivity.

Set No. 3 is an experimental arrangement using two 1N34 diode crystals in push-pull to provide louder signals than conventional crystal circuits. The coils are hand-wound to provide a split secondary winding with a primary winding between. Both primary and secondary are tuned. The dual-section variable condenser tunes the secondary of the coil to the frequency of the station. Condenser C2 in primary L3 tunes the station but it has its greatest effect on very long antennas. If the desired station operates on 850 kc. or higher, "open" the toggle switch on the bracket. Detailed student material list is R-396.

Seventh/Crown

Crown Chakra - located at the top of the head. Its function is understanding. Its inner state is: bliss. Its color is Violet and its planet is Uranus. Its stone is Amethyst. Its meditation is: I understand. Balancing this chakra is said to give vitality to the cerebrum and affects the development of psychic abilities. Energies: Air, Meditative, Intuition, Promotes thought.

Sixth/Third Eye

Third Eye Chakra - located in the center of the forehead above the eyebrows. Its function is seeing, intuiting. Its inner state is: I know. Its color is indigo and its planet is Jupiter. Its stone is: Iolite. Its meditation is: I see. Balancing this chakra helps psychic perception and balances the pineal gland. Energies: Air, Meditative, Intuition, Promotes thought.

Fifth/Throat

Throat Chakra - located in the throat Its function is communication, creativity. Its inner state is synthesis of ideas into symbols. Its color is bright blue and its planets are Mercury and Neptune. Its stones are: Sodalite, Blue Lace Agate, Lapis Lazuli. Meditation on: I speak. Balancing this chakra is important for the speech and communication areas of the brain. Energies: Water, Calming, Sooths, Relaxes.

Fourth/Heart

Heart Chakra - located in the center of the chest. Its function is: love, its inner state is compassion, love, its color is green, and its planet is Venus. Its stones are: Green/Pink Stones - Peridot, Rose Quartz, Malachite. Meditation on: I love. Balancing this chakra is important for the circulatory system, heart and thymus. It also affects spiritual love, compassion and universal oneness. Energies: Water, Calming, Soothes, Relaxes.

Third/Solar Plexus

Solar Plexus Chakra - located in the area above the navel area. Its function is Will, power, its inner state is laughter, joy, anger, its color is yellow, and its planets are Mars and the Sun. Its stones are: Amber, Topaz and Citrine. Meditation on: I do. Balancing this chakra is associated with calming emotions and frustration, easing tension and helping to better utilize intuition. Energies: Fire, Energizing, Charging, Lends Energy.

Second/Sacral

Navel/Sacral Chakra - located in the lower abdomen, genitals, womb, its function is desire, sexuality, pleasure, procreation. Its inner state is tears, its color is orange and its celestial body is the Moon. Its stones are: Coral and Carnelian. Meditation on: I feel. Balancing this chakra is associated with sexual vitality, physical power and fertility. Energies: Fire, Energizing, Charging.

First/Root Chakra

Root/support chakra - located at the base of the spine. Its function is survival and grounding, its inner state is stillness and stability, its color is red and its planets are Earth and Saturn. Its stones are: Garnet, Ruby, Onyx, Obsydian. Meditation on: I am. Balancing this chakra gives energy to the physical body, controls fear, increases overall health and helps in grounding. Energies: Earth, Grounding, Focusing, Centering.

The word chakra is Sanskrit for wheel or disk and signifies one of seven basic energy centers in the body. Each of these centers correlates to major nerve ganglia branching forth from the spinal column.

FOUNTAIN PEN CLIP SOLDERED TO CAN
TUNING KNOB
PHONE TIP-JACKS
CAN SIZE OF PACK OF CIGARETTES

ADJUSTABLE in tuning and carried in the upper breast pocket, this tiny receiver is held securely in place by an ordinary fountain-pen clip. With but two or three feet of antenna wire and a pair of head-phones one can clearly receive broadcasts within a radius of two or three miles, or within city limits. The can used to house the original set was one constructed to hold just one pack of cigarettes. Some dime stores sell them or they may be procured at cigar stores.

The circuit used is the simplest known and is shown in the diagram. It consists of a tuning coil in series with a fixed crystal and midget phone tip-jacks; the circuit being shunted by a suitable tuning condenser of the compression type commonly known as a padding condenser. Compactness is obtained mainly by utilizing a 2.5 millihenry choke, used in short wave work, as the tuning coil. The four pies, tuned by a condenser of about 250 mmfd. maximum capacity, will cover most of the broadcast band quite well.

Lay out the parts on the bench in a compact form as shown in the drawing, arranging them according to their design so they will fit into the can with the condenser tuning shaft in a position to enter a suitable hole in the upper center of the can. Any parts that may come in contact with the can should be covered with bits of electricians' tape. Wire and connect the various elements together with buss wire, if possible, to gain solidity. Fit the two phone tip-jacks in the lower edge as shown, and arrange the insulated tip-jack for the antenna in the center of the bottom (used as the top). The open top (bottom) can be closed later if desired. Grounded portions can be caught to the can with a bit of solder when the assembly finally is made. When completely assembled in the can, a short piece of brass rod can be filed and fitted into [*Continued on page 144*]

Seed Sounds in the Chakra Petals–Chakra Petal Bijas

Creation occurred due to the first sound Aum. The universe and everything in it is condensed energy, that energy is vibrating and all has sound. The body itself is sound, called sabda in Sanskrit. The body can be recreated and regenerated with sound as many modern technologies are now tapping into DNA Repair using sound waves. In the ancient Puranas (sacred story texts), there are elaborate stories of the creation of the world, this is called Shristi Karana. Meditating on the bijas (seed sounds) of the chakra petals is also called Shristi Karana, for it is the recreation of the body through sabda (sound).

VERTEBRAE	AREAS AND PARTS OF THE BODY	POSSIBLE SYMPTOMS
CERVICAL		
C 1	• Back of the head	Headaches (including migraines, aches or pain at the back of the head, behind the eyes or in the temples, tension across the forehead, throbbing or pulsating discomfort at the top or back of head)
C 2	• Various areas of the head	
C 3	• Side and front of the neck	
C 4	• Upper back of the neck	
C 5	• Middle of neck and upper part of arms	Jaw muscle, or joint aches or pains
C 6	• Lower part of neck, arms and elbows	Dizziness, nervousness, vertigo
C 7	• Lower part of arms, shoulders	Soreness, tension and tightness felt in back of neck and throat area
DORSAL		
D 1	• Hands, wrists, fingers, thyroid	Pain, soreness, and restriction in the shoulder area
D 2	• Heart, its valves and coronary arteries	Bursitis, tendonitis
D 3	• Lungs, bronchial tubes, pleura, chest	Pain and soreness in arms, hands, elbows and /or fingers
D 4	• Gall bladder, common duct	
D 5	• Liver, solar plexus	Chest pains, tightness or constriction, asthma, difficulty breathing
D 6	• Stomach, mid-back area	Middle or lower mid-back pain, discomfort and soreness
D 7	• Pancreas, duodenum	Various and numerous symptoms from trouble or malfunctioning of:
D 8	• Spleen, lower mid-back	
D 9	• Adrenal glands	– Thyroid – Heart – Lungs – Gall bladder – Liver – Stomach – Pancreas – Spleen – Adrenal glands – Kidneys
D 10	• Kidneys	
D 11	• Ureters	
D 12	• Small intestine, upper/lower back	
LUMBAR		– Small and large intestines – Sex organs – Uterus – Bladder – Prostate glands
L 1	• Ileocecal valve, large intestine	
L 2	• Appendix, abdomen, upper leg	
L 3	• Sex organs, uterus, bladder, knees	Low back pain, aches and soreness
L 4	• Prostate gland, lower back	Trouble walking
L 5	• Sciatic nerve, lower legs, ankles, feet	Leg, knee, ankle and foot weakness and pain
SACRO	• Hip bones, buttocks	Sciatica, pain or soreness in the hip and buttocks
COXIS	• Rectum, anus	Rectal trouble

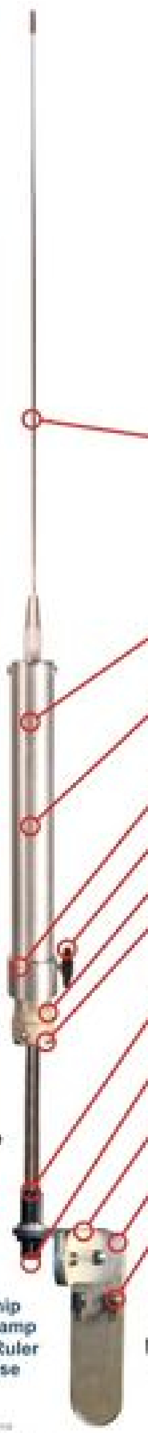
MP1RP SuperWhip

Ruggedized Antenna for HF / Pedestrian Mobile / Backpack Portable

Get the Power of a SuperWhip.



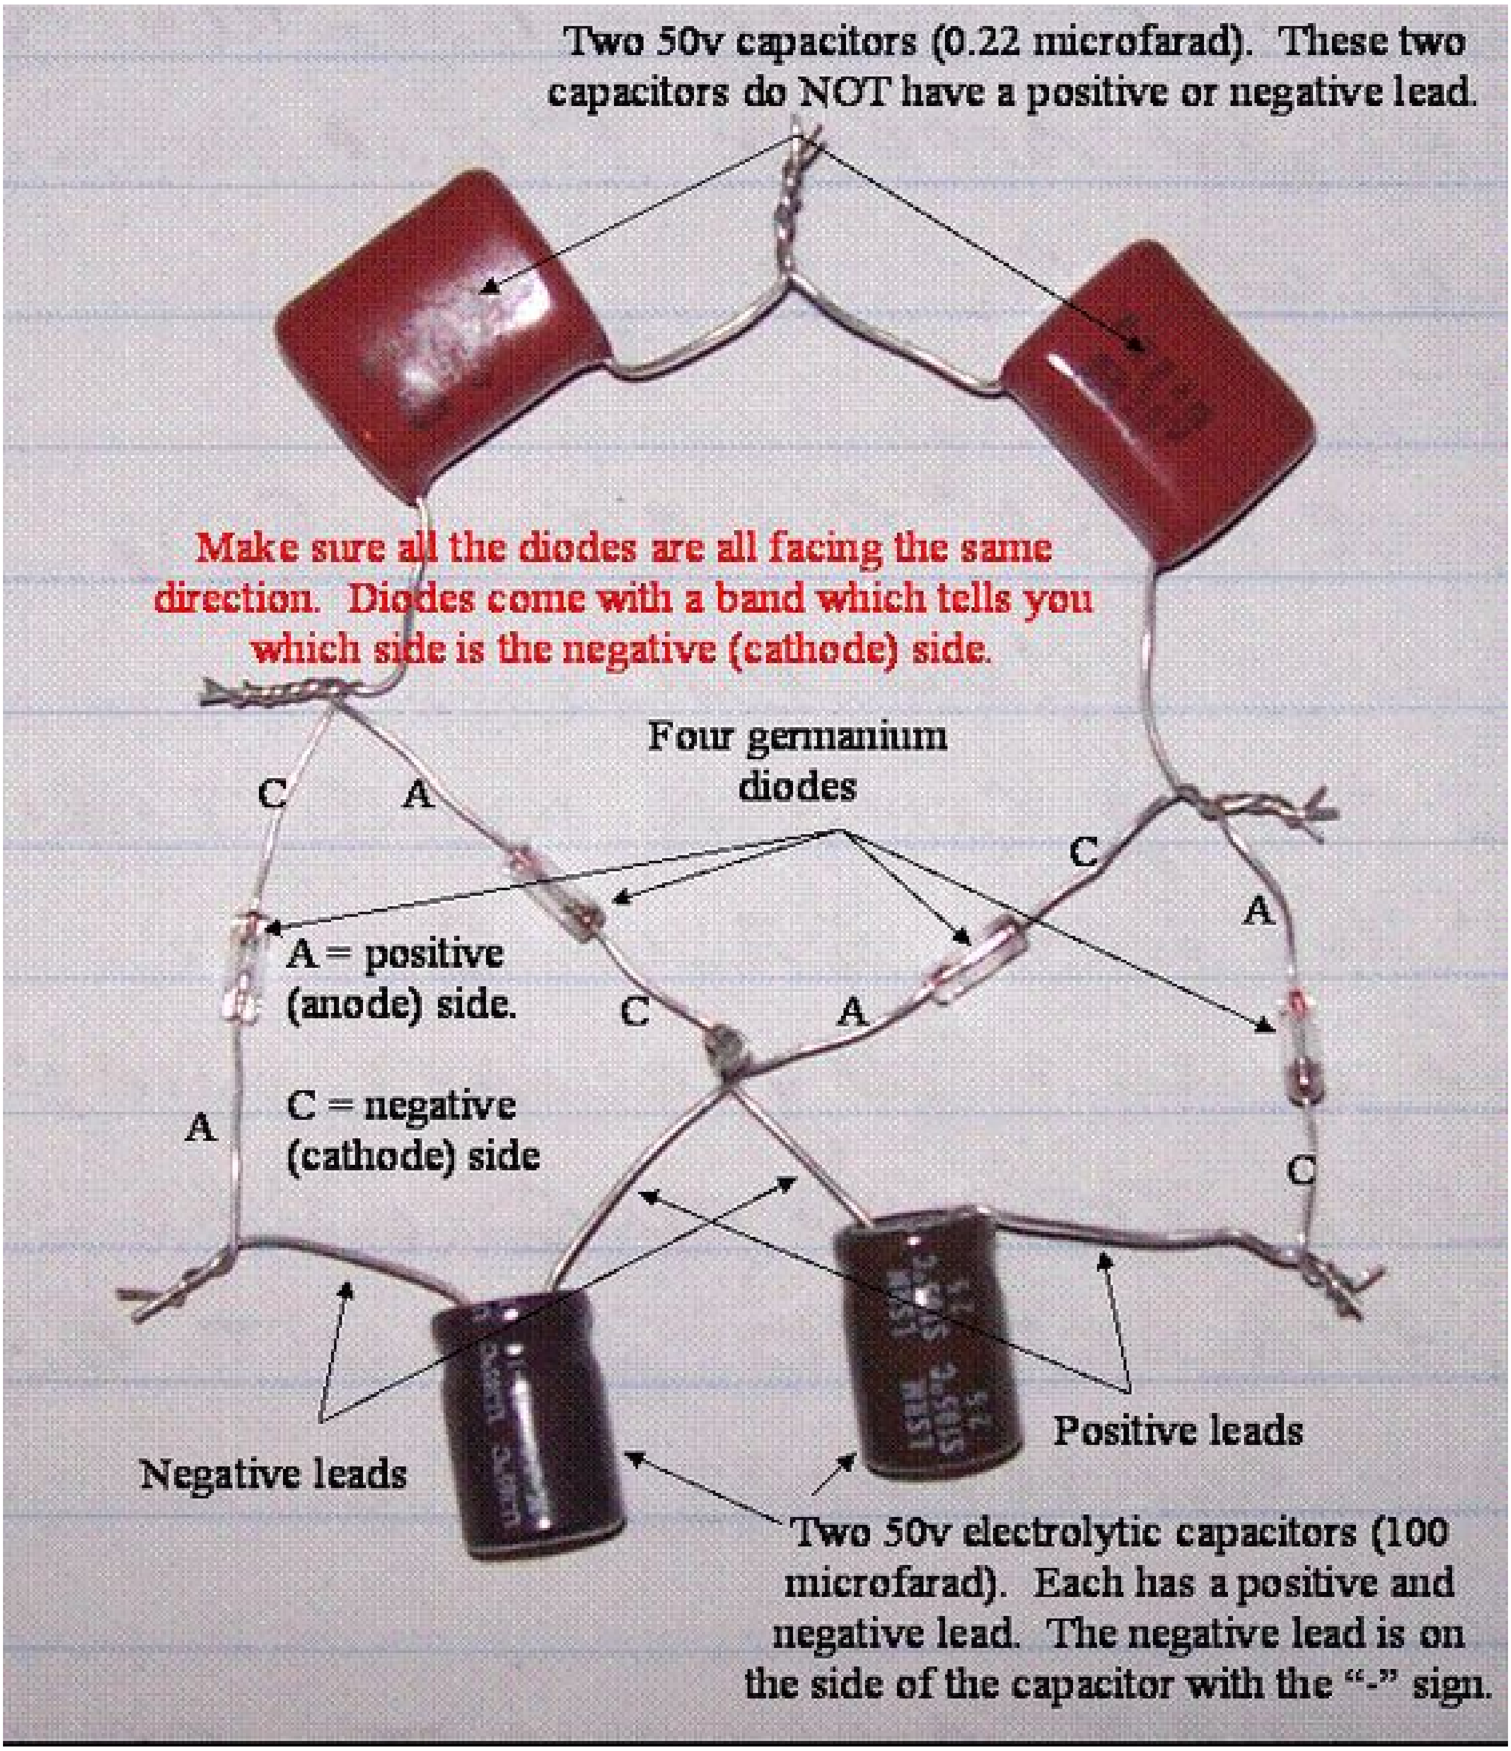
- SW1 SuperWhip
  Super Flexible Ruggedized Titanium Alloy
  Bends in a 12 inch Circle to Fit in Backpack
- All HF Bands - All Frequencies - Good SWR
- 6061-T6 Aircraft Aluminum SuperSlider
- Nickel Beryllium Weatherproof Contacts
- Tuning Lock for Secure Frequency in Motion
- High Q SuperCoil for Maximum RF Efficiency
- Durable Polymer SuperCoil Form
- All Parts Modular Standard 3/8"-24 Fittings
- Standard SO-239 Coaxial Connector
  PL-259 Compatible 50 ohms
- 360 Degree Swivel for All Positions
- UM1 SuperMount
- Dual Counterpoise Connectors
  Quick - Release Push-On
- MR1C SuperWire Stealth Teflon
  Drag Wire Counterpoise with
  Quick - Release Push-On Connectors

ER1 Extension Rod

TW1 Telescopic Whip
for VHF/UHF

CC1 Clamp For Attachments

(backpack not included)



Two 50v capacitors (0.22 microfarad). These two capacitors do NOT have a positive or negative lead.

Make sure all the diodes are all facing the same direction. Diodes come with a band which tells you which side is the negative (cathode) side.

Four germanium diodes

A = positive (anode) side.

C = negative (cathode) side

Negative leads

Positive leads

Two 50v electrolytic capacitors (100 microfarad). Each has a positive and negative lead. The negative lead is on the side of the capacitor with the "-" sign.

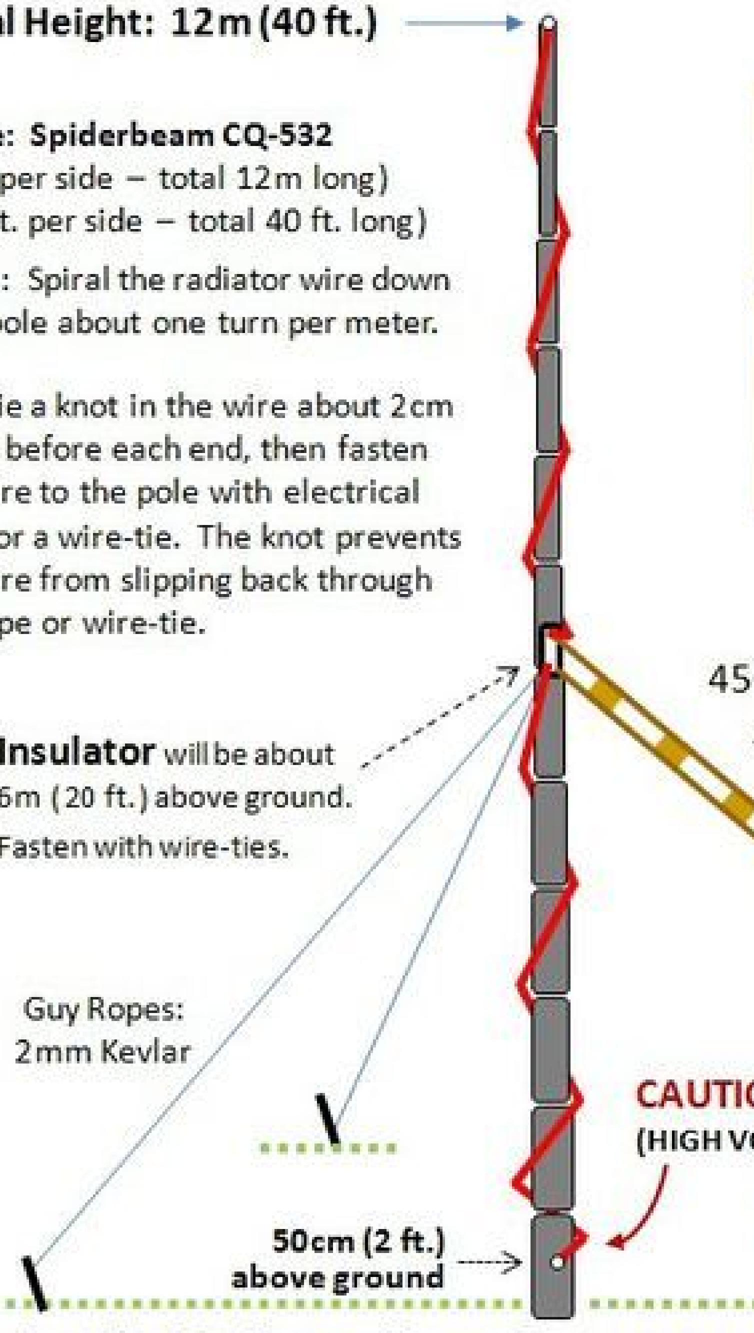
Multi-Band HF Vertical Dipole

On a Spiderbeam 12m HD Telescoping Fiberglass Pole

for: 80/40/30/20/17/15/12/10m



Total Height: 12m (40 ft.)

Wire: Spiderbeam CQ-532
(6m per side – total 12m long)
(20 ft. per side – total 40 ft. long)

Note: Spiral the radiator wire down the pole about one turn per meter.

Tip: tie a knot in the wire about 2cm (1 in.) before each end, then fasten the wire to the pole with electrical tape or a wire-tie. The knot prevents the wire from slipping back through the tape or wire-tie.

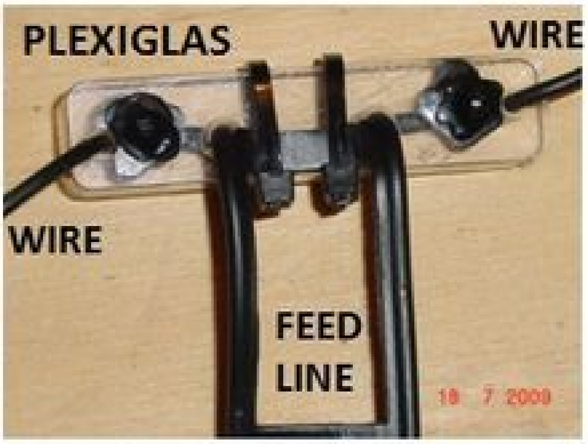
Insulator will be about 6m (20 ft.) above ground. Fasten with wire-ties.

Guy Ropes: 2mm Kevlar

50cm (2 ft.) above ground

Guy stakes 5 to 7m away from pole. (16 to 23 ft.) spaced equal distance around the pole. Or, use tree or fence to fasten ends.

CAUTION HV!
(HIGH VOLTAGE)



Simple lightweight insulator

450Ω Openwire Feedline

Although the length is not critical, there are some lengths which can cause trouble. See text.

Good Antenna Matchbox

MFJ-974B*

Guy Rope

*Alternatives described in text.

Spiraling the wire down the pole distributes its weight evenly around the pole and prevents it from flopping in the wind. Since the lower half of the pole is thicker (wider) than the upper half, the wire will end about 50cm above the ground.

IT IS IMPORTANT TO KEEP THE WIRE THIS DISTANCE FROM THE GROUND!

(57) **ABSTRACT**

A space vehicle propelled by the pressure of inflationary vacuum state is provided comprising a hollow superconductive shield, an inner shield, a power source, a support structure, upper and lower means for generating an electromagnetic field, and a flux modulation controller.

A cooled hollow superconductive shield is energized by an electromagnetic field resulting in the quantized vortices of lattice ions projecting a gravitomagnetic field that forms a spacetime curvature anomaly outside the space vehicle. The spacetime curvature imbalance, the spacetime curvature being the same as gravity, provides for the space vehicle's propulsion. The space vehicle, surrounded by the spacetime anomaly, may move at a speed approaching the light-speed characteristic for the modified locale.

SPACE VEHICLE PROPELLED BY THE PRESSURE OF INFLATIONARY VACUUM STATE

CROSS REFERENSE TO RELATED APPLICATIONS

This is a continuation of application Ser. No. 10/633,778 filed on Aug. 4, 2003, now abandoned.

TECHNICAL FIELD

The technical field of this disclosure represents space vehicles propelled by the electro-magnetically changed properties of vacuum, particularly the pressure of inflationary vacuum state.

BACKGROUND OF THE INVENTION

The existence of a magnetic-like gravitational field has been well established by physicists for general relativity, gravitational theories, and cosmology. The consequences of the effect of electromagnetically-affected gravity could be substantial and have many practical applications, particularly in aviation and space exploration.

There are methods known for converting electromagnetism into a propulsive force that potentially generates a large propulsive thrust. According to these methods, the machine thrust is produced by rotating, reciprocating masses in the following ways: centrifugal thrust, momentum thrust, and impulse thrust. ("To the Stars by Electromagnetic Propulsion", M. T. French, http://www.mtjf.demon.co.uk/antigravp2.htm#cforce).

However, the electromagnetic propulsion in an ambient space, or space that is not artificially modified, is not practical for interstellar travel because of the great distances involved. No interstellar travel is feasible without some form of distortion of space. In turn, no alteration of space is possible without the corresponding deformation of time. Gravitomagnetic alteration of space, resulting in the space-time curvature anomaly that could propel the space vehicle, could be a feasible approach to future space travel.

In the late 1940s, H. B. G. Casimir proved that the vacuum is neither particle nor field-free. It is a source of zero-point-fluctuation (ZPF) of fields such as the vacuum gravitomagnetic field. ZPF fields lead to real, measurable physical consequences such as the Casimir force. The quantized hand-made electromagnetic processes, such as those occurring in superconductors, affect the similarly quantized ZPFs. The most likely reason is the electron-positron creation and annihilation, in part corresponding to the "polarization effect" sited by Evgeny Podkletnov in explaining the gravitomagnetic effect reportedly observed by him in 1992. ("Weak Gravitational Shielding Properties of Composite Bulk $YBa_2Cu_33O_{(7-x)}$ Superconductor Below 70 K Under E.M. Field", Evgeny Podkletnov, LANL database number cond-mat/9701074, v. 3, 10 pages, 16 Sep. 1997).

The investigation of gravitomagnetism, however, started well before Podkletnov. In the U.S. Pat. No. 3,626,605, Henry Wm. Wallace describes an experimental apparatus for generating and detecting a secondary gravitational field. He also shows how a time-varying gravitomagnetic field can be used to shield the primary background of a gravitoelectric field.

In the U.S. Pat. No. 3,626,606, Henry Wm. Wallace provides a variation of his earlier experiment. A type III-V semiconductor material, of which both components have unpaired nuclear spin, is used as an electronic detector for the gravitomagnetic field. The experiment demonstrates that the material in his gravitomagnetic field circuit has hysterisis and remanence effects analogous to magnetic materials.

In the U.S. Pat. No. 3,823,570, Henry Wm. Wallace provides an additional variation of his experiment. Wallace demonstrates that, by aligning the nuclear spin of materials having an odd number of nucleons, a change in specific heat occurs.

In the U.S. Pat. No. 5,197,279, James R. Taylor discloses Electromagnetic Propulsion Engine where solenoidal windings generate an electromagnetic field that, without the conversion into a gravitomagnetic field, generates the thrust necessary for the propulsion.

In the U.S. Pat. No. 6,353,311 B1, John P. Brainard et al. offer a controversial theory of Universal Particle Flux Field, and in order to prove it empirically, provide a shaded motor-type device. This device is also intended for extracting energy from this hypothetical Field.

In the early 1980s, Sidney Coleman and F. de Luca noted that the Einsteinean postulate of a homogeneous Universe, while correct in general, ignores quantized local fluctuation of the pressure of inflationary vacuum state, this fluctuation causing local cosmic calamities. While the massless particles propagate through large portions of Universe at light speed, these anomaly bubbles, depending on their low or high relative vacuum density, cause a local increase or decrease of the propagation values for these particles. Scientists disagree about the possibility, and possible ways, to artificially create models of such anomalies.

In the early 1990s, Ning Li and D. G Torr described a method and means for converting an electromagnetic field into a gravitomagnetic field. Li and Torr suggested that, under the proper conditions, the minuscule force fields of superconducting atoms can "couple", compounding in strength to the point where they can produce a repulsion force ("Effects of a Gravitomagnetic Field on Pure Superconductors", N. Li and D. G. Torr, Physical Review, Volume 43, Page 457, 3 pages, 15 Jan. 1991).

A series of experiments, performed in the early 1990s by Podkletnov and R. Nieminen, reportedly resulted in a reduction of the weights of objects placed above a levitating, rotating superconductive disk subjected to high frequency magnetic fields. These results substantially support the expansion of Einstainean physics offered by Li & Torr. Podkletnov and Giovanni Modanese have provided a number of interesting theories as to why the weight reduction effect could have occurred, citing quantum gravitational effects, specifically, a local change in the cosmological constant. The cosmological constant, under ordinary circumstances, is the same everywhere. But, according to Podkletnov and Modanese, above a levitating, rotating superconductive disk exposed to high frequency magnetic fields, it is modified. ("Impulse Gravity Generator Based on Charged $YBa_2Cu_33O_{7-y}$ Superconductor with Composite Crystal Structure", Evgeny Podkletnov, Giovanni Modanese, arXiv.org/physics database, #0108005 volume 2, 32 pages, 8 figures, Aug. 30, 2001).

In the July 2004 paper, Ning Wu hypothesized that exponential decay of the gravitation gauge field, characteristic for the unstable vacuum such as that created by Podkletnov and Nieminen, is at the root of the gravitational shielding effects (Gravitational Shielding Effects in Gauge Theory of Gravity, Ning Wu, arXiv:hep-th/ 0307225 v 1 23 Jul. 2003, 38 pages incl. 3 figures, July 2004).

In 2002, Edward Fomalont and Sergei Kopeikin measured the speed of propagation of gravity. They confirmed that the speed of propagation of gravity matches the speed of light. ("General Relativistic Model for Experimental Measurement of the Speed of Propagation of Gravity by VLBI", S. Kopeikin and E. Fomalont, Proceedings of the 6th European VLBI Network Symposium Jun. 25–28 2002, Bonn, Germany, 4 pages).

String theory unifies gravity with all other known forces. According to String theory, all interactions are carried by fundamental particles, and all particles are just tiny loops of space itself forming the spacetime curvature. Gravity and bent space are the same thing, propagating with the speed of light characteristic of the particular curvature. In light of the Fomalont and Kopeikin discovery, one can conclude that if there is a change in the speed of propagation of gravity within the spacetime curvature, then the speed of light within the locality would also be affected.

In general relativity, any form of energy affects the gravitational field, so the vacuum energy density becomes a potentially crucial ingredient. Traditionally, the vacuum is assumed to be the same everywhere in the Universe, so the vacuum energy density is a universal number. The cosmological constant Λ is proportional to the vacuum pressure ρ_Λ: $\Lambda=(8\pi G/3c^2)\rho_\Lambda$, where G is Newton's constant of gravitation and c is the speed of light ("The Cosmological Constant", Sean M. Carroll, http://pancake.uchicago.edu/~carroll/encyc/, 6 pages). Newer theories, however, permit local vacuum fluctuations where even the "universal" constants are affected: $\Lambda_1=(8\pi G_1/3c_1^2)\rho_{\Lambda_1}$.

Analyzing physics laws defining the cosmological constant, a conclusion can be drawn that, if a levitating, rotating superconductive disk subjected to high frequency magnetic fields affects the cosmological constant within a locality, it would also affect the vacuum energy density. According to the general relativity theory, the gravitational attraction is explained as the result of the curvature of spacetime being proportional to the cosmological constant. Thus, the change in the gravitational attraction of the vacuum's subatomic particles would cause a local anomaly in the curvature of the Einsteinean spacetime.

Time is the fourth dimension. Lorentz and Einstein showed that space and time are intrinsically related. Later in his life, Einstein hypothesized that time fluctuates both locally and universally. Ruggero Santilli, recognized for expanding relativity theory, has developed the isocosmology theory, which allows for variable rates of time. Time is also a force field only detected at speeds above light speed. The energy of this force field grows as its propagation speed declines when approaching light-speed. Not just any light-speed: the light-speed of a locale. If the conditions of the locale were modified, this change would affect the local time rate relative to the rate outside the affected locale, or ambient rate. The electromagnetically-generated gravitomagnetic field could be one such locale modifier.

Analyzing the expansion of Einstainean physics offered by Li & Torr, one could conclude that gravity, time, and light speed could be altered by the application of electromagnetic force to a superconductor.

By creating a spacetime curvature anomaly associated with lowered pressure of inflationary vacuum state around a space vehicle, with the lowest vacuum pressure density located directly in front of the vehicle, a condition could be created where gravity associated with lowered vacuum pressure density pulls the vehicle forward in modified spacetime.

By creating a spacetime curvature anomaly associated with elevated pressure of inflationary vacuum state around the space vehicle, with the point of highest vacuum pressure density located directly behind the vehicle, a condition could be created where a repulsion force associated with elevated vacuum pressure density pushes the space vehicle forward in modified spacetime. From the above-mentioned cosmological constant equation, re-written as:

$$\rho_\Lambda = \frac{3c^2}{8\pi G}\Lambda$$

it is clear that the increase in the vacuum pressure density could lead to a substantial increase in the light-speed. If the space vehicle is moving in the anomaly where the local light-speed is higher than the light-speed of the ambient vacuum, and if this vehicle approaches this local light-speed, the space vehicle would then possibly exceed the light-speed characteristic for the ambient area.

The levitating and rotating superconductor disk, which Podkletnov used to protect the object of experiment from the attraction produced by the energy of the vacuum, was externally energized by the externally-powered solenoid coils. Thus, Podkletnov's system is stationary by definition and not suitable for travel in air or space. Even if the superconductive disk is made part of the craft, and if it is energized by the energy available on the craft, the resulting anomaly is one-sided, not enveloping, and not providing the variable speed of light (VSL) environment for the craft.

In a recent (2002) article, Chris Y. Tailor and Modanese propose to employ an impulse gravity generator directing, from an outside location, an anomalous beam toward a spacecraft, this beam acting as a repulsion force field producing propulsion for the spacecraft. ("Evaluation of an Impulse Gravity Generator Based Beamed Propulsion Concept", Chris Y. Taylor and Giovanni Modanese, American Institute of Aeronautics and Astronautics, Inc., 2002, 21 pages, 10 figures). The authors of the article, however, didn't take into account the powerful quantized processes of field dispersion, which would greatly limit the distance of propagation of the repulsive force. At best, the implementation of this concept could assist in acceleration and deceleration at short distances from the impulse gravity generator, and only along a straight line of travel. If the travel goal is a space exploration mission rather than the shuttle-like commute, the proposed system is of little use.

Only a self-sufficient craft, equipped with the internal gravity generator and the internal energy source powering this generator, would have the flexibility needed to explore new frontiers of space. The modification of the spacetime curvature all around the spacecraft would allow the spacecraft to approach the light-speed characteristic for the modified locale, this light-speed, when observed from a location in the ambient space, being potentially many times higher than the ambient light-speed. Then, under sufficient local energies, that is, energies available on the spacecraft, very large intergalactic distances could be reduced to conventional planetary distances.

In "The First Men in the Moon" (1903), H. G. Wells anticipates gravitational propulsion methods when he describes gravity repelling "cavorite." Discovered by Professor Cavor, the material acts as a "gravity shield" allowing Cavor's vehicle to reach the Moon. Prof. Cavor built a large spherical gondola surrounded on all sides by cavorite shutters that could be closed or opened. When Prof. Cavor closed all the shutters facing the ground and opened the shutters facing the moon, the gondola took off for the Moon.

Until today, no cavorite has been discovered. However, recent research in the area of superconductivity, nanomaterials and quantum state of vacuum, including that of Li, Torr, Podkletnov, and Modanese, has resulted in important new information about the interaction between a gravitational field and special states of matter at a quantum level. This new research opens the possibility of using new electromagnetically-energized superconductive materials allowing stable states of energy, the materials useful not only in controlling the local gravitational fields, but also in creating new gravitomagnetic fields.

BACKGROUND OF INVENTION: OBJECTS AND ADVANTAGES

There are four objects of this invention:

The first object is to provide a method for generating a pressure anomaly of inflationary vacuum state that leads to electromagnetic propulsion.

The second object is to provide a space vehicle capable of electromagnetically-generated propulsion. The implementation of these two objects leads to the development of the space vehicle propelled by gravitational imbalance with gravity pulling, and/or antigravity pushing, the space vehicle forward.

The third object is to provide a method for generating a pressure anomaly of inflationary vacuum state, specifically, the local increase in the level of vacuum pressure density associated with the greater curvature of spacetime. The speed of light in such an anomaly would be higher than the speed of light in the ambient space.

The fourth object is to provide the space vehicle capable of generating an unequally-distributed external anomaly all around this vehicle, specifically the anomaly with the elevated level of vacuum pressure density. The anomaly is formed in such a way that gravity pulls the space vehicle forward in the modified spacetime at a speed possibly approaching the light-speed specific for this modified locale. If the vacuum pressure density of the locale is modified to be substantially higher than that of the ambient vacuum, the speed of the vehicle could conceivably be higher than the ambient light-speed.

SUMMARY OF THE INVENTION

This invention concerns devices self-propelled by the artificially changed properties of the pressure of inflationary vacuum state to speeds possibly approaching the light-speed specific for this modified locale. Furthermore, this invention concerns devices capable of generating the spacetime anomaly characterized by the elevated vacuum pressure density. The devices combining these capabilities may be able to move at speeds substantially higher than the light-speed in the ambient space.

The device of this invention is a space vehicle. The outside shell of the space vehicle is formed by a hollow disk, sphere, or the like hollowed 3-dimensional shape made of a superconductor material, hereinafter a hollow superconductive shield. An inner shield is disposed inside the hollow superconductive shield. The inner shield is provided to protect crew and life-support equipment inside.

A support structure, upper means for generating an electromagnetic field and lower means for generating an electromagnetic field are disposed between the hollow superconductive shield and the inner shield. A flux modulation controller is disposed inside the inner shield to be accessible to the crew.

Electrical energy is generated in a power source disposed inside the hollow superconductive shield. The electrical energy is converted into an electromagnetic field in the upper means for generating an electromagnetic field and the lower means for generating an electromagnetic field.

Electrical motors, also disposed inside the hollow superconductive shield, convert the electrical energy into mechanical energy.

The mechanical energy and the electromagnetic field rotate the hollow superconductive shield, and the upper and the lower means for generating an electromagnetic field, against each other.

The electromagnetic field is converted into a gravitomagnetic field in the hollow superconductive shield.

The gravitomagnetic field, propagated outward, orthogonally to the walls of the hollow superconductive shield, forms a pressure anomaly of inflationary vacuum state in the area of propagation. The pressure anomaly of inflationary vacuum state is comprised of an area of relatively lower vacuum pressure density in front of the space vehicle and an area of relatively higher vacuum pressure density behind the vehicle.

The difference in the vacuum pressure density propels the space vehicle of this invention forward.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a cross-sectional view through the front plane taken along the central axis of a space vehicle provided by the method and device of this invention.

FIGS. **2**A & **2**B are diagrams, presented as perspective views, showing some of the physical processes resulting from a dynamic application of an electromagnetic field to a hollow superconductive shield. Only one line of quantized vortices, shown out of scale, is presented for illustration purposes.

FIGS. **3**A & **3**B are diagrams, presented as perspective views, showing a vacuum pressure density anomaly associated with lowered pressure of inflationary vacuum state and a vacuum pressure density anomaly associated with elevated pressure of inflationary vacuum state, respectively. Both anomalies are shown on the background of Universal curvature of inflationary vacuum state.

FIGS. **4**A & **4**B are diagrams, presented as perspective views, showing a spacetime anomaly associated with lowered pressure of inflationary vacuum state and a spacetime anomaly associated with elevated pressure of inflationary vacuum state, respectively. Both anomalies are shown on the background of Universal spacetime.

FIGS. **5**A, **5**B, **6**, **7**A, & **7**B are diagrams of spacetime curvature anomalies generated by the space vehicle of the current invention, these anomalies providing for the propulsion of the space vehicle.

DESCRIPTION OF THE PRESENTLY PREFERRED EMBODIMENT

FIG. **1** is a cross-sectional view through the front plane taken along the central axis of a space vehicle provided by the method and device of this invention. A hollow superconductive shield **1** forms a protective outer shell of the space vehicle. The hollow superconductive shield **1** may be shaped as a hollow disk, sphere, or the like 3-dimensional geometrical figure formed by the 2-dimensional rotation of a curve around the central axis.

In the preferred embodiment, the hollow superconductive shield **1** is made of a superconductor such as YBa2Cu3O7-y, or a like high-temperature superconductor with a composite crystal structure cooled to the temperature of about 40 degrees K. The skilled in the art may envision the use of many other low- and high-temperature superconductors, all within the scope of this invention.

An inner shield **2** is disposed inside the hollow superconductive shield **1**. The inner shield **2** is comprised of an upper shell **3** and a lower shell **4**, the shells **3** and **4** adjoined with each other. Executed from insulation materials such as foamed ceramics, the inner shield **2** protects the environment within the shield from the electromagnetic field and severe temperatures.

A support structure **5** is disposed between the hollow superconductive shield **1** and the inner shield **2**, concentric to the hollow superconductive shield. The support structure **5** is comprised of an upper rotating element **6** and a lower rotating element **7**.

The upper rotating element **6** is pivotably disposed inside the hollow superconductive shield **1** and may envelope the upper shell **3**. The lower rotating element **7** is pivotably disposed inside the hollow superconductive shield **1** and may envelope the lower shell **4**. Even though the preferred embodiment has two rotating elements, a skilled in the art may envision only one rotating element, or three or more rotation elements, all within the scope of this invention.

Upper means for generating an electromagnetic field **8** are disposed between the hollow superconductive shield **1** and the upper shell **3**. The upper means for generating an electromagnetic field **8** are affixed to the upper rotating element **6** at an electromagnetic field-penetrable distance to the hollow superconductive shield **1**.

Lower means for generating an electromagnetic field **9** are disposed between the hollow superconductive shield **1** and the lower shell **4**. The lower means for generating an electromagnetic field **9** are affixed to the lower rotating element **7** at an electromagnetic field-penetrable distance to the hollow superconductive shield **1**.

The upper means for generating an electromagnetic field **8** and the lower means for generating an electromagnetic field **9** could be solenoid coils or electromagnets. In the process of operation of the space vehicle, the electromagnetic field identified by flux lines **10**, is controllably and variably applied to the hollow superconductive shield **1**.

Electric motors are disposed inside the hollow superconductive shield along its central axis.

A power source **11** is disposed inside the hollow superconductive shield **1** and may be disposed inside the lower shell **4**. The power source **11** is electrically connected with the upper means for generating an electromagnetic field **8**, the lower means for generating an electromagnetic field **9**, and the electric motors. In-turn, the upper means for generating an electromagnetic field **8**, the lower means for generating an electromagnetic field **9**, and the electric motors provide for the rotation of the upper rotating element **6** and the lower rotating element **7**. The power source **11** may be executed as a nuclear power generator.

Life-support equipment **12** is disposed inside the inner shield **2**, and may be disposed inside the lower shell **4**. The life-support equipment **12** may include oxygen, water, and food.

A flux modulation controller **13** is disposed inside the inner shield **2**, and may be disposed inside the upper shell **3**. The flux modulation controller **13** is in communication with the upper means for generating an electromagnetic field **8**, the lower means for generating an electromagnetic field **9**, the power source **11**, and the electric motors.

The flux modulation controller **8** may be executed as a computer or a microprocessor. The flux modulation controller **8** is provided with a capability of modulating the performance parameters of the upper means for generating an electromagnetic field **8**, the lower means for generating an electromagnetic field **9**, the power source **11**, and the electric motors.

A crew **14** may be located inside the upper shell **3** of the inner shield **2** and may consist of one or more astronauts. The crew has a free access to the life-support equipment **12** and the flux modulation controller **8**. A skilled in the art may envision a fully-automated, pilotless craft, which is also within the scope of this invention.

A skilled in the art may also envision the embodiment (not shown), also within the scope of this invention, where the hollow superconductive shield is pivotable, and the support structure with the means for generating an electromagnetic field is affixed on the outside of the inner shield.

FIGS. **2**A & **2**B are diagrams showing the results of the quantized electromagnetic turbulence within the superconductive shell of the hollow superconductive shield provided by the relative rotational motion of the hollow superconductive shield against the upper means for generating an electromagnetic field.

FIG. **2A** shows the clockwise relative rotational motion of the hollow superconductive shield, this motion identified by a clockwise shield motion vector **15**, and the counterclockwise relative rotational motion of upper means for generating an electromagnetic field, this motion identified by a counterclockwise EMF motion vector **16**.

The electromagnetic field, controllably and variably applied by the upper means for generating an electromagnetic field, whose various positions are identified by a wire grid **17**, to the hollow superconductive shield (not shown), causes quantized electromagnetic turbulence within the hollow superconductive shield. This turbulence is represented by a plurality of clockwise quantized vortices of lattice ions **18**. Only one line of the clockwise quantized vortices of lattice ions **18**, out of scale, is shown for illustration purposes only. Each of the clockwise quantized vortices of lattice ions **18** generates a gravitomagnetic field identified by an outward gravitomagnetic field vector **19** directed orthogonally away from the hollow superconductive shield.

FIG. **2B** shows the counterclockwise relative rotational motion of the hollow superconductive shield, this motion identified by a counterclockwise shield motion vector **20**, and the clockwise relative rotational motion of upper means for generating an electromagnetic field, this motion identified by a clockwise EMF motion vector **21**.

The electromagnetic field, controllably and variably applied by the upper means for generating an electromagnetic field identified by the wire grid **17**, to the hollow superconductive shield (not shown), causes quantized electromagnetic turbulence within the hollow superconductive shield, this turbulence represented by a plurality of counterclockwise quantized vortices of lattice ions **22**. Only one line of the counterclockwise quantized vortices of lattice ions **22**, out of scale, is shown for illustration purposes only. Each of the counterclockwise quantized vortices of lattice ions **22** generates a gravitomagnetic field identified by an inward gravitomagnetic field vector **23** directed orthogonally toward the hollow superconductive shield.

The electrical requirements for providing the Li-Torr effect are as follows:

Podkletnov has reported using the high frequency current of 10^5 Hz. He also used 6 solenoid coils @ 850 Gauss each. The reported system's efficiency reached 100% and the total field in the Podkletnov's disk was about 0.5 Tesla. The maximum weight loss reported by Podkletnov was 2.1%.

The preferred embodiment of the device of current invention is capable of housing 2–3 astronauts and therefore is envisioned to be about 5 meters in diameter at the widest point. The preferred space vehicle's acceleration is set at 9.8 m/s/s providing that gravity on board is similar to that on the surface of Earth.

The means for generating an electromagnetic field may be comprised of 124 solenoid coils. At the same 100% efficiency reported by Podkletnov, the total field required providing the acceleration of 9.8 m/s/s is 5,000 Tesla, or about 40 Tesla per coil. Skeggs suggests that on the Podkletnov device, out of 850 Gauss developed on the coil surface, the field affecting the superconductor and causing the gravitomagnetism is only 400 Gauss ("Engineering Analysis of the Podkletnov Gravity Shielding Experiment, Peter L. Skeggs, Quantum Forum, Nov. 7, 1997, http://www.inetarena.com/~noetic/pls/podlev.html, 7 pages). This translates into 47% device efficiency.

In this 47%-efficient space vehicle, the total field required achieving the 9.8 m/s/s acceleration is about 10,600 Tesla, or 85.5 Tesla per each of 124 solenoid coils. It must be noted that at this acceleration rate, it would take nearly a year for the space vehicle to reach the speed of light.

It also must be noted that Skeggs has detected a discrepancy between the Li-Torr estimates and Podkletnov's practical results. If Podkletnov's experimental results are erroneous while the Li-Torr estimates are indeed applicable to the space vehicle of this invention, then the energy requirements for achieving the sought speed would be substantially higher than the above estimate of 10,600 Tesla.

Podkletnov has concluded that, in order for the vacuum pressure density anomaly to take place, the Earth-bound device must be in the condition of Meissner levitation. As are all space bodies, the space vehicle is a subject to the pressure inflationary vacuum state and the gravitational force, which, within the migrating locality of the expanding Universe, in any single linear direction, are substantially in equilibrium. Thus, for the space vehicle, the requirement of Meissner levitation is waved.

The propagation of the gravitomagnetic field identified by the outward gravitomagnetic field vector **19** and the inward gravitomagnetic field vector **23** would cause exotic quantized processes in the vacuum's subatomic particles that include particle polarization, ZPF field defects, and the matter-energy transformation per $E=mc^2$. The combination of these processes would result in the gravitational anomaly. According to the general relativity theory, gravitational attraction is explained as the result of the curvature of spacetime being proportional to the gravitational constant. Thus, the change in the gravitational attraction of the vacuum's subatomic particles would cause a local anomaly in the curvature of the Einsteinean spacetime.

Gravity is the same thing as bent space, propagating with the speed of light characteristic for the particular spacetime curvature. When bent space is affected, there is a change in the speed of propagation of gravity within the spacetime curvature anomaly. The local speed of light, according to Fomalont and Kopeikin always equal to the local speed of propagation of gravity, is also affected within the locality of spacetime curvature anomaly.

Creation of spacetime curvature anomalies adjacent to, or around, the space vehicle, these anomalies characterized by the local gravity and light-speed change, has been the main object of this invention.

FIG. **3A** shows a diagram of a vacuum pressure density anomaly associated with lowered pressure of inflationary vacuum state **24** on the background of Universal curvature of inflationary vacuum state **25**. The vacuum pressure density anomaly associated with lowered pressure of inflationary vacuum state **24** is formed by a multitude of the inward gravitomagnetic field vectors. According to the cosmological constant equation, $\Lambda=(8\pi G/3c^2)\rho_\Lambda$, where the cosmological constant Λ is proportional to the vacuum energy pressure ρ_Λ, G is Newton's constant of gravitation, and c is the speed of light, the curvature of spacetime is proportional to the gravitational constant. According to the general relativity theory, the change in the vacuum pressure density is proportional to the change in the spacetime curvature anomaly. By replacing ρ_Λ with the vacuum pressure density, P times the vacuum energy coefficient κ, and replacing c with Δdistance/Δtime, we derive to $\Lambda=[8\pi G/3(\Delta\text{distance}/\Delta\text{time})^2]P_\kappa$, and could now construct a vacuum pressure density curvature diagram.

The vacuum pressure density curvature anomaly associated with lowered pressure of inflationary vacuum state **24** is shown here as a flattened surface representing the lowered pressure of the inflationary vacuum state. This anomaly is the result of the exotic quantized processes in the subatomic particles caused by the quantized turbulence occurring in the hollow superconductive shield. The XYZ axes represent three dimensions of space and the P axis represents the vacuum pressure density.

FIG. **3**B shows a diagram of a vacuum pressure density anomaly associated with elevated pressure of inflationary vacuum state **26** on the background of the Universal curvature of inflationary vacuum state **25**. The vacuum pressure density anomaly associated with elevated pressure of inflationary vacuum state **26** is formed by a multitude of the outward gravitomagnetic field vectors. The anomaly is shown here as a convex surface representing the elevated pressure of inflationary vacuum state. The diagrams of FIGS. **3**A & **3**B are not to scale: the anomaly sizes are exaggerated for clarity.

FIGS. **4**A & **4**B show diagrams of a spacetime anomaly associated with lowered pressure of inflationary vacuum state **27**, and a spacetime anomaly associated with elevated pressure of inflationary vacuum state **28**, respectively, each on the background a diagram of Universal spacetime **29**.

The quaterized Julia set $Q_{n+1}=Q_n^2+C_0$ is assumed to be an accurate mathematical representation of the Universal spacetime. The generic quaternion Q_0 belongs to the Julia set associated with the quaternion C, and n tends to infinity. If we assume that the quaternion value C_0 is associated with the Universal spacetime **29**, C_1 is the value of quaternion C for the spacetime anomaly associated with lowered pressure of inflationary vacuum state **27**, and C_2 is the value of quaternion C for the spacetime anomaly associated with elevated pressure of inflationary vacuum state **28**, then we can construct two diagrams.

The diagram of FIG. **4**A shows the spacetime anomaly associated with lowered pressure of inflationary vacuum state **27** as a quaterized Julia set contained in a 4-dimensional space: $Q_{n+1}=Q_n^2+C_1$ on the background of the Universal spacetime **29** represented by $Q_{n+1}=Q_n^2+C_0$.

The diagram of FIG. **4**B shows the spacetime anomaly associated with elevated pressure of inflationary vacuum state **28** as a quaterized Julia set $Q_{n+1}=Q_n^2+C_2$, also on the background of the Universal spacetime **29** represented by $Q_{n+1}=Q_n^2+C_0$. On both diagrams, the XYZ axes represent three dimensions of space, and the T axis represents time. The diagrams are not to scale: the anomaly sizes are exaggerated for clarity, and the halves of quaterized Julia sets, conventionally associated with the hypothetical Anti-Universe, are omitted.

FIGS. **5**A, **5**B, **6**, **7**A, & **7**B show simplified diagrams of spacetime curvature anomalies generated by the space vehicle of the current invention, these anomalies providing for the propulsion of the space vehicle. In each case, the pressure anomaly of inflationary vacuum state is comprised of an area of relatively lower vacuum pressure density in front of the space vehicle and an area of relatively higher vacuum pressure density behind the space vehicle. Because the lower pressure of inflationary vacuum state is associated with greater gravity and the higher pressure is associated with the higher repulsive force, the space vehicle is urged to move from the area of relatively higher vacuum pressure density toward the area of relatively lower vacuum pressure density.

FIG. **5**A illustrates the first example of spacetime curvature modification. This example shows a substantially droplet-shaped spacetime curvature anomaly associated with lowered pressure of inflationary vacuum state **30** adjacent to the hollow superconductive shield **1** of the space vehicle. The anomaly **30** is provided by the propagation of a gravitomagnetic field radiating orthogonally away from the front of the hollow superconductive shield **1**. This gravitomagnetic field may be provided by the relative clockwise motion of the upper means for generating an electromagnetic field, and relative counterclockwise motion of the hollow superconductive field, as observed from above the space vehicle.

In this example, the difference between the spacetime curvature within the substantially droplet-shaped spacetime anomaly associated with lowered pressure of inflationary vacuum state, and the ambient spacetime curvature, the spacetime curvature being the same as gravity, results in the gravitational imbalance, with gravity pulling the space vehicle forward.

FIG. **5**B illustrates the second example of spacetime curvature modification. This example shows a substantially droplet-shaped spacetime anomaly associated with elevated pressure of inflationary vacuum state **31** adjacent to the hollow superconductive shield **1** of the space vehicle. The anomaly **31** is provided by the propagation of a gravitomagnetic field radiating orthogonally away from the back of the hollow superconductive shield. This gravitomagnetic field may be provided by the relative counterclockwise motion of the lower means for generating an electromagnetic field, and relative clockwise motion of the hollow superconductive field, as observed from below the space vehicle.

In this example, the difference between the spacetime curvature within the substantially droplet-shaped spacetime anomaly associated with elevated pressure of inflationary vacuum state, and the ambient spacetime curvature, the spacetime curvature being the same as gravity, results in the gravitational imbalance, with the repulsion force pushing the space vehicle forward.

FIG. **6** illustrates the third example of spacetime curvature modification. This example shows the formation of the substantially droplet-shaped spacetime anomaly associated with lowered pressure of inflationary vacuum state **30** combined with the substantially droplet-shaped spacetime anomaly associated with elevated pressure of inflationary vacuum state **31**. This combination of anomalies may be provided by the relative clockwise motion of the upper means for generating an electromagnetic field and relative clockwise motion of the hollow superconductive field, combined with the relative clockwise motion of the lower means for generating an electromagnetic field, as observed from above the space vehicle.

In this example, the difference between the spacetime curvature within the substantially droplet-shaped spacetime anomaly associated with lowered pressure of inflationary vacuum state, and the spacetime curvature of the substantially droplet-shaped spacetime anomaly associated with elevated pressure of inflationary vacuum state, the spacetime curvature being the same as gravity, results in the gravitational imbalance, with gravity pulling, and the repulsion force pushing, the space vehicle forward.

FIG. **7**A illustrates the fourth example of spacetime curvature modification. This example shows the formation of a substantially egg-shaped spacetime anomaly associated with lowered pressure of inflationary vacuum state **32** around the hollow superconductive shield **1** of the space vehicle. The anomaly **32** is provided by the propagation of gravitomagnetic field of unequally-distributed density, this gravitomagnetic field radiating in all directions orthogonally away from the hollow superconductive shield. The propagation of the unequally-distributed gravitomagnetic field leads to the similarly unequally-distributed spacetime curvature anomaly. This unequally-distributed gravitomagnetic field may be provided by the relatively faster clockwise motion of the upper means for generating an electromagnetic field relative to the hollow superconductive field, combined with the relatively slower counterclockwise motion of the lower means for generating an electromagnetic field, as observed from above the space vehicle.

An area of the lowest vacuum pressure density **33** of the substantially egg-shaped spacetime anomaly associated with lowered pressure of inflationary vacuum state **32** is located directly in front of the space vehicle.

In this example, the variation in the spacetime curvature within the substantially egg-shaped spacetime anomaly associated with lowered pressure of inflationary vacuum state, the spacetime curvature being the same as gravity, results in a gravitational imbalance, with gravity pulling the space vehicle forward in modified spacetime.

FIG. **7**B illustrates the fifth example of spacetime curvature modification, also with the purpose of providing for a propulsion in modified spacetime. This example shows the formation of a substantially egg-shaped spacetime anomaly associated with elevated pressure of inflationary vacuum state **34** around the hollow superconductive shield **1** of the space vehicle. The anomaly **34** is provided by the propagation of gravitomagnetic field of unequally-distributed density, this gravitomagnetic field radiating in all directions orthogonally away from the hollow superconductive shield. The propagation of the unequally-distributed gravitomagnetic field leads to the similarly unequally-distributed spacetime curvature anomaly. This unequally-distributed gravitomagnetic field may be provided by the relatively slower counterclockwise motion of the upper means for generating an electromagnetic field relative to the hollow superconductive field, combined with the relatively faster clockwise motion of the lower means for generating an electromagnetic field, as observed from above the space vehicle.

An area of the highest vacuum pressure density **35** of the substantially egg-shaped spacetime anomaly associated with elevated pressure of inflationary vacuum state **34** is located directly behind the space vehicle.

In this example, the variation in the spacetime curvature within the substantially egg-shaped spacetime anomaly associated with elevated pressure of inflationary vacuum state, the spacetime curvature being same as gravity, results in a gravitational imbalance, with the repulsion force pushing the space vehicle forward in modified spacetime at speeds approaching the light-speed characteristic for this modified area. This light-speed might be much higher than the light-speed in the ambient space.

By creating alternative anomalies and modulating their parameters, the space vehicle's crew would dilate and contract time and space on demand. The space vehicle, emitting a vacuum pressure modifying, controllably-modulated gravitomagnetic field in all directions, would rapidly move in the uneven spacetime anomaly it created, pulled forward by gravity or pushed by the repulsion force. The time rate zone of the anomaly is expected to have multiple quantized boundaries rather than a single sudden boundary affecting space and time in the immediate proximity of the vehicle. Speed, rate of time, and direction in space could be shifted on demand and in a rapid manner. The modulated light-speed could make the space vehicle suitable for interstellar travel. Because of the time rate control in the newly created isospace, the accelerations would be gradual and the angles of deviation would be relatively smooth. The gravity shielding would further protect pilots from the ill-effects of gravity during rapid accelerations, directional changes, and sudden stops.

What is claimed is:

1. A space vehicle propelled by the pressure of inflationary vacuum state is claimed comprising:

a hollow superconductive shield,

an inner shield, the inner shield disposed inside said hollow superconductive shield, said inner shield comprising an upper shell and a lower shell,

a support structure, the support structure disposed between said hollow superconductive shield and said inner shield concentrically to said hollow superconductive shield, said support structure comprised of an upper rotating element and a lower rotating element,

upper means for generating an electromagnetic field, the upper means for generating an electromagnetic field disposed between said hollow superconductive shield and said upper shell, affixed to said upper rotating element at an electromagnetic field-penetrable distance to said hollow superconductive shield,

lower means for generating an electromagnetic field, the lower means for generating an electromagnetic field disposed between said hollow superconductive shield and said lower shell, affixed to said lower rotating element at an electromagnetic field-penetrable distance to said hollow superconductive shield,

electric motors, the electric motors disposed inside said hollow superconductive shield along the central axis of said hollow superconductive shield,

a power source, the power source disposed inside said hollow superconductive shield, said power source electrically connected with said upper means for generating an electromagnetic field, said lower means for generating an electromagnetic field, and said electric motors,

life-support equipment, the life-support equipment disposed inside said inner shield,

a flux modulation controller, the flux modulation controller disposed inside said inner shield, said flux modulation controller in communication with said upper means for generating an electromagnetic field, said lower means for generating an electromagnetic field, said power source, and said electric motors, and

a crew, the crew disposed inside said inner shield accessibly to said life-support and said flux modulation controller.

2. The space vehicle of claim **1** wherein said hollow superconductive shield is composed of a high-temperature ceramic superconductor with a composite crystal structure, and is cooled to a temperature of about 40 degrees K.

3. The space vehicle of claim **1** wherein said inner shield is composed of insulating materials such as foamed ceramics.

4. The space vehicle of claim **1** wherein said power source is a nuclear generator.

5. The space vehicle of claim **1** wherein said flux modulation controller is a computer.

6. The space vehicle of claim **1** wherein said upper rotating element and said lower rotating element are pivoted, urged to rotate by said upper means for generating an electromagnetic field, said lower means for generating an electromagnetic field, and said electric motors.

7. The space vehicle of claim **1** wherein said hollow superconductive shield is pivoted and urged to rotate by said upper means for generating an electromagnetic field, said lower means for generating an electromagnetic field, and said electric motors.

8. A method for generating pressure anomaly of inflationary vacuum state is claimed comprising the following steps, some occurring simultaneously:

providing a space vehicle comprising a hollow superconductive shield, an inner shield, a support structure, upper means for generating an electromagnetic field, lower means for generating an electromagnetic field, electric motors, a power source, life-support equipment, a flux modulation controller, and a crew,

generating electrical energy in said power source,

converting said electrical energy into an electromagnetic field in said upper means for generating an electromagnetic field and said lower means for generating an electromagnetic field,

converting said electrical energy into mechanical energy in said electrical motors,

rotating said upper means for generating an electromagnetic field and said lower means for generating an electromagnetic field relative to said hollow superconductive shield,

converting said electromagnetic field into a gravitomagnetic field in said hollow superconductive shield,

propagating said gravitomagnetic field outward, orthogonal to the walls of said hollow superconductive shield, and

forming a pressure anomaly of inflationary vacuum state in the area of propagation of said gravitomagnetic field, the pressure anomaly of inflationary vacuum state comprised of an area of relatively lower vacuum pressure density in front of said space vehicle and an area of relatively higher vacuum pressure density behind said vehicle,

whereby said space vehicle is urged to move from said area of relatively higher vacuum pressure density toward said area of relatively lower vacuum pressure density.

9. The method of claim **8** wherein said pressure anomaly of inflationary vacuum state is a substantially droplet-shaped anomaly associated with lowered pressure of inflationary vacuum state provided by the propagation of a gravitomagnetic field radiating orthogonally away from the front of said hollow superconductive shield,

whereby providing for the gravitational imbalance where the lowered pressure of inflationary vacuum state is pulling said space vehicle forward.

10. The method of claim **8** wherein said pressure anomaly of inflationary vacuum state is a substantially droplet-shaped anomaly associated with elevated pressure of inflationary vacuum state provided by the propagation of a gravitomagnetic field radiating orthogonally away from the back of said hollow superconductive shield,

whereby providing for the gravitational imbalance where the elevated pressure of inflationary vacuum state is pushing said space vehicle forward.

11. The method of claim **8** wherein said pressure anomaly of inflationary vacuum state is comprised of a substantially droplet-shaped anomaly associated with lowered pressure of inflationary vacuum state and a substantially droplet-shaped anomaly associated with elevated pressure of inflationary vacuum state,

whereby providing for the gravitational imbalance where the lowered pressure of inflationary vacuum state is pulling, and the elevated pressure of inflationary vacuum state is pushing, said space vehicle forward.

12. The method of claim **8** wherein said pressure anomaly of inflationary vacuum state is a substantially egg-shaped anomaly associated with lowered pressure of inflationary vacuum state provided by the unequally-distributed gravitomagnetic field propagated in all directions orthogonally away from said hollow superconductive shield with an area of lowest vacuum pressure density disposed directly in front said space vehicle,

whereby providing for the gravitational imbalance such that the lowered pressure of inflationary vacuum state is pulling said space vehicle forward in modified space-time.

13. The method of claim **8** wherein said pressure anomaly of inflationary vacuum state is a substantially egg-shaped anomaly associated with elevated pressure of inflationary vacuum state provided by the unequally-distributed gravitomagnetic field propagated in all directions orthogonally away from said hollow superconductive shield with an area of highest vacuum pressure density disposed directly behind said space vehicle,

whereby providing for the gravitational imbalance such that the highest pressure of inflationary vacuum state is pushing said space vehicle forward in modified space-time at a speed possibly approaching a local light-speed, the local light-speed which may be substantially higher than the light-speed in the ambient space.

United States Patent No. 4,858,612—*Hearing Device*:

> ABSTRACT
>
> A method and apparatus for simulation of hearing in mammals by introduction of a plurality of microwaves into the region of the auditory cortex... A microphone is used to transform sound signals into electrical signals which are in turn analyzed and processed to provide controls for generating a plurality of microwave signals at different frequencies. The multifrequency microwaves are then applied to the brain in the region of the auditory cortex. By this method sounds are perceived by the mammal which are representative of the original sound perceived by the microphone.

You will not find a better description of the means by which voices can be electronically transmitted into a human mind. Although the text of the patent presents the invention as a therapeutic aid for individuals who have hearing impairments, the potential mind control applications of the device are obvious.

But why stop at the mere electronic transmission of voices into the human brain? Why not electronically alter the brain waves themselves by means of radio transmissions? Consider, for example, United States Patent No. 3,951,134 – *Apparatus and Method for Remotely Monitoring and Altering Brain Waves*. The abstract says:

> ABSTRACT
> Apparatus for and method of sensing brain waves at a position remote from a subject whereby electromagnetic signals of different frequencies are simultaneously transmitted to the brain of the subject in which the signals interfere with one another to yield a waveform which is modulated by the subject's brain waves. The interference waveform which is representative of the brain wave activity is re-transmitted by the brain to a receiver where it is demodulated and amplified. The demodulated waveform is then displayed for visual viewing and routed to a computer for further processing and analysis. The demodulated waveform also can be used to produce a compensating signal which is transmitted back to the brain to effect a desired change in electrical activity therein.

Quoting again from the text of the patent:

> SUMMARY OF THE INVENTION
> The present invention relates to apparatus and a method for monitoring brain waves wherein all components of the apparatus employed are remote from the test subject. More specifically, high frequency transmitters are operated to radiate electromagnetic energy of different frequencies through antennas which are capable of scanning the entire brain of the test subject or any desired region thereof. The signals of different frequencies penetrate the skull of the subject and impinge upon the brain where they mix to yield an interference wave modulated by radiations from the brain's natural electrical activity. The modulated interference wave is re-transmitted by the brain and received by an antenna at a remote station where it is demodulated, and processed to provide a profile of the subject's brain waves. In addition to passively monitoring his brain waves, the subject's neurological processes may be affected by transmitting to his brain, through a transmitter, compensating signals. The latter signals can be derived from the received and processed brain waves.

The import of the invention could not be clearer. This patent spells out, in black and white, an electronic method and apparatus for remotely monitoring and altering the brain waves of human beings, by use of radio transmitters and computers. The subject's brain waves are electronically monitored, received, routed to a computer, modified, and then transmitted back to his/her brain, with the stated intention of altering the "electrical activity" of the subject's brain. As the patent states:

> ... the subject's neurological processes may be affected by transmitting to his brain, through a transmitter, compensating signals. The latter signals can be derived from the received and processed brain waves.

The potential for electronic mind control is transparent.

Thanks to modern electronic technology the electrical activity of the human brain can be precisely monitored and displayed. The subtle electromagnetic fields and accompanying electrical activity in the brain can be electronically monitored and recorded in real time. United States Patent No. 4,951,674—*Biomagnetic Analytical System Using Fiber-Optic Magnetic Sensors* describes one such method and apparatus:

> ABSTRACT
> A biomagnetic analytical system for sensing and indicating minute magnetic fields emanating from the brain or from any other tissue region of interest in a subject under study. The system includes a magnetic pickup device constituted by an array of fiber-optic magnetic sensors mounted at positions distributed throughout the inner confines of a magnetic shield configured to conform generally to the head of the subject or what-

> ever other body region is of interest. Each sensor yields a light beam whose phase or other parameter is modulated in accordance with the magnetic field emanating from the related site in the region. The modulated beam from each sensor is compared in an interferometer with a reference light beam to yield an output signal that is a function of the magnetic field being emitted at the related site. The output signals from the interferometer are processed to provide a display or recording exhibiting the pattern or map of magnetic fields resulting from emanations at the multitude of sites encompassed by the region.

This device makes possible the mapping of the brain's biomagnetic activity. The data can be displayed visually, on a CRT monitor (as on a computer screen), permitting a specialist to electronically peer into a person's head and to:

> ..."see" a functional image of the brain on a CRT, ... the image will be a profile of the electromganetically "active" portions of the brain, as shown by the magnetic pattern derived from data reduction...

The data can also be digitized for subsequent storage and manipulation. In the words of the patent:

> The data can also be directed to a storage medium for the purpose of recording the digitized biomagnetic data for archiving and later retrieval and processing.

Patent No. 4,951,674 goes on to say that during the data processing stage, data from:

> ... modalities such as EEG, EKG, MRI and X-ray ... can be combined with the biomagnetic data ...

In other words, the practitioner can reconcile the biomagnetic data with an individual's EEG pattern. This means a specific pattern of biomagnetic activity can be correlated with a particular pattern of electrical activity in the brain. (See the appendix at the end of the book for the complete patent. Look at illustrations 1 to 3. Note the special helmet with the magnetic sensors that fits around the head of the person whose brain's biomagnetic activity is being monitored and digitally recorded.)

United States Patent No. 4,408,616, *Brain Electrical Activity Mapping*, provides further information on how the human brain can be electronically monitored.

The patent abstract says, in part:

> Topographic displays of brain electrical activity are produced from matrices of data derived from evoked potential (EP) and steady-state responses of skull transducers ... the rate of data sampling is sufficient to capture rapid transient events ...

In other words, the transition from one mental state to another can be observed and electronically mapped. The text of the patent explains how this is done:

> Twenty electrodes (e.g., Grass gold cup) are attached to subject's skull ... Twenty leads from electrodes are connected through switch to conventional 24-channel polygraph ...

The patent succinctly explains how electrodes are attached to a person's skull and connected to a polygraph machine to record the electrical activity of their brain in real time, as it responds to various stimuli. It neatly sums up:

> ... (T)he brain electrical activity mapping system creates color topographic displays reflecting brain electrical activity using, as input, continuous electrical waveforms recorded from a number of points on the skull.

The data are then converted to digital form. Data are stored in individual files or combined with others into "group" files, so that a group profile of brain electrical activity in response to a variety of stimuli can be constructed. The stimulus may be a flashing light or something more complex, like being asked to distinguish between two similar, but slightly different, spoken words.

Over time, a library of digitized data (data that can be stored and analyzed by computer) about the electrical activity of the brains of individual people and groups of people is built up. This is precisely the type of data that can be used to modulate a radio wave that is transmitted into a target subject's brain to alter his/her brainwaves. In principle, by using averaged data derived from group files of brain electrical activity, it should be possible to modulate radio broadcasts to affect the brain electrical activity of large numbers of a target population.

In many cases people's minds and brains have been tampered with and altered without their informed consent. Psychoactive drugs, microwaves, hypnosis, brain washing and electronic implants are some of the ways in which mind control victims have been attacked by these shadowy agencies.

Electronic and psychotronic mind control technologies are absolutely antithetical to the fundamental exercise of human freedom. Unfortunately, the patents and technologies described here are real. It is time for us all to wake up and see things as they are. A particularly insidious slavery is mental enslavement, accomplished by electronically or psychotronically altering people's thoughts, such that their very thoughts are not their own, but are ones that their self-appointed masters would have them to think.

[57] **ABSTRACT**

A method and apparatus for simulation of hearing in mammals by introduction of a plurality of microwaves into the region of the auditory cortex is shown and described. A microphone is used to transform sound signals into electrical signals which are in turn analyzed and processed to provide controls for generating a plurality of microwave signals at different frequencies. The multifrequency microwaves are then applied to the brain in the region of the auditory cortex. By this method sounds are perceived by the mammal which are representative of the original sound received by the microphone.

HEARING DEVICE

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to devices for aiding of hearing in mammals. The invention is based upon the perception of sounds which is experienced in the brain when the brain is subjected to certain microwave radiation signals.

2. Description of the Prior Art

In prior art hearing devices for human beings, it is well known to amplify sounds to be heard and to apply the amplified sound signal to the ear of the person wearing the hearing aid. Hearing devices of this type are however limited to hearing disfunctions where there is no damage to the auditory nerve or to the auditory cortex. In the prior art, if there is damage to the auditory cortex or the auditory nerve, it cannot be corrected by the use of a hearing aid.

During World War II, individuals in the radiation path of certain radar installations observed clicks and buzzing sounds in response to the microwave radiation. It was through this early observation that it became known to the art that microwaves could cause a direct perception of sound within a human brain. These buzzing or clicking sounds however were not meaningful, and were not perception of sounds which could otherwise be heard by the receiver. This type of microwave radiation was not representative of any intelligible sound to be perceived. In such radar installations, there was never a sound which was generated which resulted in subsequent generation of microwave signals representative of that sound.

Since the early perception of buzzing and clicking, further research has been conducted into the microwave reaction of the brain. In an article entitled "Possible Microwave Mechanisms of the Mammalian Nervous System" by Philip L. Stocklin and Brain F. Stocklin, published in the TIT Journal of Life Sciences, Tower International Technomedical Institute, Inc. P.O. Box 4594, Philadelphia, Pa. (1979) there is disclosed a hypothesis that the mammalian brain generates and uses electro magnetic waves in the lower microwave frequency region as an integral part of the functioning of the central and peripheral nervous systems. This analysis is based primarily upon the potential energy of a protein integral in the neural membrane.

In an article by W. Bise entitled "Low Power Radio-Frequency and Microwave Effects On Human Electroencephalogram and Behavior", Physiol. Chemistry Phys. 10, 387 (1978), it is reported that there are significant effects upon the alert human EEG during radiation by low intensity CW microwave electromagnetic energy. Bise observed significant repeatable EEG effects for a subject during radiation at specific microwave frequencies.

SUMMARY OF THE INVENTION

Results of theoretical analysis of the physics of brain tissue and the brain/skull cavity, combined with experimentally-determined electromagnetic properties of mammalian brain tissue, indicate the physical necessity for the existence of electromagnetic standing waves, called modes in the living mammalian brain. The mode characteristics may be determined by two geometric properties of the brain: these are the cephalic index of the brain (its shape in prolate spheroidal coordinates) and the semifocal distance of the brain (a measure of its size). It was concluded that estimation of brain cephalic index and semifocal distance using external skull measurements on subjects permits estimation of the subject's characteristic mode frequencies, which in turn will permit a mode by mode treatment of the data to simulate hearing.

This invention provides for sound perception by individuals who have impaired hearing resulting from ear damage, auditory nerve damage, and damage to the auditory cortex. This invention provides for simulation of microwave radiation which is normally produced by the auditory cortex. The simulated brain waves are introduced into the region of the auditory cortex and provide for perceived sounds on the part of the subject.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows the acoustic filter bank and mode control matrix portions of the hearing device of this invention.

FIG. 2 shows the microwave generation and antenna portion of the hearing device of this invention.

FIG. 3 shows a typical voltage divider network which may be used to provide mode partition.

FIG. 4 shows another voltage divider device which may be used to provide mode partition.

FIG. 5 shows a voltage divider to be used as a mode partition wherein each of the resistors is variable in order to provide adjustment of the voltage outputs.

FIG. 6 shows a modified hearing device which includes adjustable mode partitioning, and which is used to provide initial calibration of the hearing device.

FIG. 7 shows a group of variable oscillators and variable gain controls which are used to determine hearing characteristics of a particular subject.

FIG. 8 shows a top view of a human skull showing the lateral dimension.

FIG. 9 shows the relationship of the prolate spherical coordinate system to the cartesian system.

FIG. 10 shows a side view of a skull showing the medial plane of the head, section A—A.

FIG. 11 shows a plot of the transverse electric field amplitude versus primary mode number M.

FIG. 12 shows a left side view of the brain and auditory cortex.

FIG. 13 shows the total modal field versus angle for source location.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

This invention is based upon observations of the physical mechanism the mammalian brain uses to perceive acoustic vibrations. This observation is based in part upon neuro anatomical and other experimental evidence which relates to microwave brain stimulation and the perception of sounds.

It is has been observed that monochromatic acoustic stimuli (acoustic tones, or single tones) of different frequencies uniquely stimulate different regions of the cochlea. It has also been observed that there is a corresponding one to one relationship between the frequency of a monochromatic acoustic stimulus and the region of the auditory cortex neurally stimulated by the cochlear nerve under the physiologically normal conditions (tonotopicity).

It is has been observed that for an acoustic tone of a frequency which is at the lower end of the entire acoustical range perceivable by a person, that a thin lateral region ("Line") parallel to the medial axis of the brain and toward the inferior portion of the primary auditory cortex is stimulated. For an acoustic tone whose frequency is toward the high end of the entire perceivable acoustic range, a thin lateral region parallel to the medial axis and toward the superior portion of the primary auditory cortex is stimulated.

Neural stimulation results in the generation of a broad band of microwave photons by the change in rotational energy state of protons integral to the neuron membrane of the auditory cortex. The physical size and shape of the brain/skull cavity, together with the (semiconductor) properties (conductivity and dielectric constant) of the brain tissue provide an electromagnetic resonant cavity. Specific single frequencies are constructively reinforced so that a number of standing electromagnetic waves, each at its own single electromagnetic frequency in the microwave frequency region, are generated in the brain. Each such standing electromagnetic wave is called a characteristic mode of the brain/skull cavity.

Analysis in terms of prolate spheroidal wave functions indicates that transverse electric field components of these modes have maxima in the region of the auditory cortex. This analysis further shows that transverse electric field possess a variation of amplitude with angle in the angular plane (along the vertical dimension of the auditory cortex) and that is dependent only upon the primary mode number.

The auditory cortex in the normally functioning mammalian brain is a source of microwave modes. The auditory cortex generates these modes in accordance with the neural stimulation of the auditory cortex by the cochlear nerve. Mode weighting for any one acoustic tone stimulus is given by the amplitude of each mode along the line region of the auditory cortex which is neurally stimulated by that acoustic tone stimulus. A listing of mode weighting versus frequency of acoustic stimulus is called the mode matrix.

In this invention, the functions of the ear, the cochlear nerve, and the auditory cortex are simulated. Microwaves simulating the mode matrix are inserted directly into the region of the auditory cortex. By this insertion of simulated microwave modes, the normal operation of the entire natural hearing mechanism is simulated.

Referring now to FIG. 1 and FIG. 2 there is shown an apparatus which provides for induced perception of sound into a mammalian brain. This hearing device includes a microphone 10 which receives sounds, an acoustic filter bank 12 which separates the signals from the microphone into component frequencies, and a mode control matrix 14 which generates the mode signals which are used to control the intensity of microwave radiations which are injected into the skull cavity in the region of the auditory cortex.

The acoustic filter bank 12 consists of a bank of acoustic filters F1 through Fk which span the audible acoustic spectrum. These filters may be built from standard resistance, inductance, and capacitance components in accordance with well established practice. In the preferred embodiment there are 24 filters which correspond to the observed critical bandwidths of the human ear. In this preferred embodiment a typical list of filter parameters is given by Table I below:

TABLE I

Filter No.	Center Frequency (Hz)	Bandwidth (Hz)
1	50	less than 100
2	150	100
3	250	100
4	350	100
5	450	110
6	570	120
7	700	140
8	840	150
9	1,000	160
10	1,170	190
11	1,370	210
12	1,600	240
13	1,850	280
14	2,150	320
15	2,500	380
16	2,900	450
17	3,400	550
18	4,000	700
19	4,800	900
20	5,800	1,100
21	7,000	1,300
22	8,500	1,800
23	10,500	2,500
24	13,500	3,500

The rectifier outputs one through K are feed to K mode partition devices. The mode partitioning devices each have N outputs wherein N is the number of microwave oscillators used to generate the microwave radiation. The outputs 1 through N of each mode partition device is applied respectively to the inputs of each gain controlled amplifier of the microwave radiation generator. The function of the mode control matrix 14 is the control of the microwave amplifiers in the microwave amplifier bank 18. In the preferred embodiment thus will be 24 outputs and 24 microwave frequency oscillators.

Connected to each microwave amplifier gain control line is a mode simulation device 16 which receives weighted mode signals from the mode partition devices 14. Each mode simulation device consists of one through k lines and diodes 17 which are each connected to summing junction 19. The diodes 17 provide for isolation from one mode partition device to the next. The diodes 17 prevent signals from one mode partition device from returning to the other mode partition devices which are also connected to the same summing junction of the mode summation device 16. The diodes also serve a second function which is the rectification of the signals received from the acoustic filter bank by way of the mode partition devices. In this way each mode partition device output is rectified to produce a varying DC voltage with major frequency components of the order of 15 milliseconds or less. The voltage at the summation junction 19 is thus a slowly varying DC voltage.

The example mode partition devices are shown in greater detail in FIGS. 3, 4, and 5. The mode partition devices are merely resistance networks which produce 1 through N output voltages which are predetermined divisions of the input signal from the acoustic filter associated with the mode partition device. FIG. 3 shows a mode partitioning device wherein several outputs are associated with each series resistor 30. In the embodiment depicted in FIG. 4 there is an output associated with each series resistor only, and thus there are N series resistors, or the same number of series resistors as there are outputs. The values of the resistors in the mode partition resistor network are determined in accordance with the magnitudes of the frequency component from the acoustic filter bank 12 which is required at the summation point 19 or the gain control line for amplifiers 20.

The microwave amplifier bank 18 consists of a plurality of microwave oscillators 1 through N each of which is connected to an amplifier 20. Since the amplifiers 20 are gain controlled by the signals at summation junction 19, the magnitude of the microwave output is controlled by the mode control matrix outputs F1 through F_n. In the preferred embodiment there are 24 amplifiers.

The leads from the microwave oscillators 1 through N to the amplifiers 20 are shielded to prevent cross talk from one oscillator to the next, and to prevent stray signals from reaching the user of the hearing device. The output impedance of amplifiers 20 should be 1000 ohms and this is indicated by resistor 21. The outputs of amplifiers 20 are all connected to a summing junction 22. The summing junction 22 is connected to a summing impedance 23 which is approximately 50 ohms. The relatively high amplifier output impedance 21 as compared to the relatively low summing impedance 23 provides minimization of cross talk between the amplifiers. Since the amplitude of the microwave signal needed at the antenna 24 is relatively small, there is no need to match the antenna and summing junction impedances to the amplifier 20 output impedances. Efficiency of the amplifiers 20 is not critical.

Level control of the signal at antenna 24 is controlled by pick off 25 which is connected to the summing impedance 23. In this manner, the signal at antenna 24 can be varied from 0 (ground) to a value which is acceptable to the individual.

The antenna 24 is placed next to the subject's head and in the region of the subject's auditory cortex 26. By placement of the antenna 24 in the region of the auditory cortex 26, the microwave field which is generated simulates the microwave field which would be generated if the acoustic sounds were perceived with normal hearing and the auditory cortex was functioning normally.

In FIG. 2A there is shown a second embodiment of the microwave radiation and generator portion of the hearing device. In this embodiment a broad band microwave source 50 generates microwave signals which are feed to filters 52 through 58 which select from the broad band radiation particular frequencies to be transmitted to the person. As in FIG. 2, the amplifiers 20 receive signals on lines 19 from the mode control matrix. The signals on lines 19 provide the gain control for amplifiers 20.

In FIG. 6 there is shown a modified microwave hearing generator 60 which includes a mode partition resistor divider network as depicted in FIG. 5. Each of the mode partition voltage divider networks in this embodiment are individually adjustable for all of the resistances in the resistance network. FIG. 5 depicts a voltage division system wherein adjustment of the voltage partition resistors is provided for.

In FIG. 6, the sound source 62 generates audible sounds which are received by the microphone of the microwave hearing generator 60. In accordance with the operation described with respect to FIGS. 1 and 2, microwave signals are generated at the antenna 10 in accordance with the redistribution provided by the mode control matrix as set forth in FIG. 5.

The sound source 62 also produces a signal on line 64 which is received by a head phone 66. The apparatus depicted in FIG. 6 is used to calibrate or fit a microwave hearing generator to a particular individual. Once the hearing generator is adjusted to the particular individual by adjustment of the variable resistors in the adjustable mode partition portion of the hearing generator, a second generator may be built using fixed value resistors in accordance with the adjusted values achieved in fitting the device to the particular subject. The sound produced by headphone 66 should be the same as a sound from the sound source 62 which is received by the microphone 10 in the microwave hearing generator 60. In this way, the subject can make comparisons between the perceived sound from the hearing generator 60, and the sound which is heard from headphone 66. Sound source 62 also produces a signal on 68 which is feed to cue light 69. Cue light 69 comes on whenever a sound is emitted from sound source 62 to the microwave generator 60. In this manner, if the subject hears nothing, he will still be informed that a sound has been omitted and hence that he is indeed perceiving no sound from the microwave hearing generator 60.

In FIG. 7 there is shown a modified microwave hearing generator which may be used to determine a subject's microwave mode frequencies. In this device, the acoustic filter bank and the mode control matrix have been removed and replaced by voltage level signal generated by potentiometers 70. Also included are a plurality of variable frequency oscillators 72 which feed microwave amplifiers 74 which are gain controlled from the signal generated by potentiometers 70 and pick off arm 76.

This modified microwave hearing generator is used to provide signals using one oscillator at a time. When an oscillator is turned on, the frequency is varied about the estimated value until a maximum acoustic perception by the subject is perceived. This perception however may consist of a buzzing or hissing sound rather than a tone because only one microwave frequency is being received. The first test of perception is to determine the subject's lowest modal frequency for audition $(M=1)$. Once this modal frequency is obtained, the process is repeated for several higher modal frequencies and continued until no maximum acoustic perception occurs.

Another method of determination of a subject's modal frequencies is through anatomical estimation. This procedure is by measurement of the subject's cephalic index and the lateral dimensions of the skull. In this method, the shape is determined in prolate spheroidal coordinance.

Purely anatomical estimation of subject's modal frequencies is performed by first measuring the maximum lateral dimension (breadth) L FIG. 8, of the subject's head together with the maximum dimension D (anterior to posterior) in the medial plane of the subject's head. D is the distance along Z axis as shown in FIG. 10. The ratio L/D, called in anthropology the cephalic index, is monotonically related to the boundary value ξ_0 defining the ellipsoidal surface approximating the interface between the brain and the skull in the prolate spheroidal coordinate system. ξ_0 defines the shape of this interface: ξ_0 and D together give an estimate of a, the semi-focal distance of the defining ellipsoid. Using ξ_0 and a, together with known values of the conductivity and dielectric constants of brain tissue, those wavelengths are found f[illegible] which the radial component of the electric [illegible]s the boundary condition that it is zero at ξ_0.

These wavelengths are the wavelengths associated with the standing waves or modes; the corresponding frequencies are found by dividing the phase velocity of microwaves in brain tissue by each of the wavelengths.

A subject's microwave modal frequencies may also be determined by observing the effect of external microwave radiation upon the EEG. The frequency of the M equal 1 mode may then be used as a base point to estimate all other modal frequencies.

A typical example of such an estimation is where the subject is laterally irradiated with a monochromatic microwave field simultaneous with EEG measurement and the microwave frequency altered until a significant change occurs in the EEG, the lowest such frequency causing a significant EEG change is found. This is identified as the frequency of the $M=1$ mode, the lowest mode of importance in auditory perception. The purely anatomical estimation procedure (FIGS. 8, 9, 10) is then performed and the ratio of each modal frequency to the $M=1$ modal frequency obtained. These ratios together with the experimentally-determined $M=1$ frequency are then used to estimate the frequencies of the mode numbers higher than 1. The prolate spheroidal coordinate system is shown in FIG. 9. Along the lateral plane containing the x and y coordinates of FIG. 9, the prolate spheroidal coordinate variable ϕ (angle) lies FIGS. 9 and 10. Plots of the transverse electric field amplitude versus primary mode number m are shown in FIG. 11. The equation is

$$E_{transverse}(m, \phi) = E_o \sin(m\,\phi)$$

The "elevation view" FIG. 12, of the brain from the left side, shows the primary auditory cortex 10. The isotone lines and the high frequency region are toward the top of 100 and the low frequency region toward the bottom of 100.

The formula I, set forth below is the formula for combining modes from an iso-tone line at $\phi=\phi j$ being excited to obtain the total modal field at some other angular location ϕ. For this formula, if we let $J=1$ (just one iso-tone single frequency acoustic stimulus line), then it can be shown that ALL modes (in general) must be used for any ONE tone.

FORMULA I
RMS TRANSVERSE ELECTRIC FIELD IN ANGULAR PLANE, f(0)

$$f(0) = \left[\sum_{m=1}^{M}\left(\sin(m0)\cdot\sum_{j=1}^{J} e^{-(0-0_j)/\Delta 0_m}\sin(m0_j)\right)^{2}\right]^{\frac{1}{2}}$$

ϕ = ANGLE (0° LATERAL)
ϕ_j = LOCATION OF j-TH SOURCE (TOTAL NUMBER J)
$\Delta\phi_m$ = ATTENUATION LENGTH (IN ANGLE) OF m-TH MODE
m = PRIMARY MODE NUMBER (HIGHEST MODE M)

FIG. 13 shows the resulting total modal field versus angle ϕ for source location ϕ at 5.25°, 12.5°, etc. With reference to the set of curves at the left top of this figure. A spacing of approximately 7.25° in ϕ corresponds to a tonal difference of about 1 octave. This conclusion is based on the side-lobes of pattern coming from $\phi=5.25°$, etc. The total filed (value on y-axis) falls considerably below the top curves for source locations well below 5.25° (toward the high acoustic stimulus end) and also as the source of frequency goes well above 30° (low frequency end). ϕ is plotted positive downward from 0° at lateral location as indicates in FIG. 11.

Resistor weightings are obtained from the $|\sin(m[\phi-\phi j])|$, Formula I. The scale between acoustic frequency and ϕ must be set or estimated from experiment. Approximately 5.25±1° corresponds to a tonal stimulus at about 2 kHz (the most sensitive region of the ear) since this source location gives the highest electric field amplitude.

The apparatus of FIG. 7 may also be used to determine values for a hearing device which are required for a particular subject. Once the modal frequencies have been estimated, the device of FIG. 7 which includes variable microwave oscillators may be used to determine values for the oscillators which match the subject, and to determine resistance values associated with the mode partition devices of the mode control matrix.

In FIG. 7 manual control of the amplifier gain is achieved by potentiometers 76. In this manner the amplifier gains are varied about the estimated settings for an acoustic tone stimulus in the region of two thousand Hertz (2 kHz) until maximum acoustic perception and a purest tone are achieved together. The term purest tone may also be described as the most pleasing acoustic perception by the subject. This process may be repeated at selected frequencies above and below 2 kHz. The selected frequencies correspond to regions of other acoustic filter center frequencies of the subject. When modal frequency (oscillator frequency) and gain set values (setting a potentiometer 76) are noted, it is then possible to calculate fixed oscillator frequencies and control resistor values for the adjusted hearing device for this particular subject.

In the event the subject has no prior acoustic experience, that is deaf from birth, estimated resistor values must be used. Also, a complex acoustic stimulation test including language articulation and pairs of harmonically related tones may be developed to maximize the match of the hearing device parameters for those of this particular subject.

Typical components for use in this invention include commercially available high fidelity microphones which have a range of 50 Hz to 15 kHz with plus or minus 3 dB variation.

The audio filters to be used with the acoustic filter bank 12 are constructed in a conventional manner, and have Q values of about 6. The filters may also be designed with 3 dB down points (½ the bandwidth away from the center frequency) occurring at adjacent center frequency locations.

The diodes 17 in the mode control matrix which provide isolation between the mode partition circuits are commercially available diodes in the audio range.

The microwave oscillators 1 through N and the microwave amplifiers 20 are constructed with available microwave transistors which can be configured either as oscillators or amplifiers. Examples of the transistors are GaAsFET field effect transistors by Hewlitt Packard known as the HFET series or silicone bipolar transistors by Hewlitt Packard known as the HXTR series.

All the cable between the oscillators, the microwave amplifiers, and the antenna should be constructed with either single or double shielded coaxial cable.

The antenna 24 for directing microwave signals to the audio cortex 26 should be approximately the size of the auditory cortex. A typical size would be one and

16

one half CM high and one half to one CM wide. The antenna as shown is located over the left auditory cortex, but the right may also be used. Since the characteristic impedance of the brain tissue at these microwave frequencies is close to 50 ohms, efficient transmission by commercially available standard 50 ohm coax is possible.

The invention has been described in reference to the preferred embodiments. It is, however, to be understood that other advantages, features, and embodiments may be within the scope of this invention as defined in the appended claims.

What is claimed is:

1. A sound perception device for providing induced perception of sound into a mammalian brain comprising in combination:

means for generating microwave radiation which is representative of a sound to be perceived, said means for generating including means for generating a simultaneous plurality of microwave radiation frequencies and means for adjusting the amplitude of said microwave radiation frequencies in accordance with the sound to be perceived; and

antenna means located in the region of the auditory cortex of said mammalian brain for transmitting said microwave energy into the auditory cortex region of said brain.

2. A hearing device for perception of sounds comprising in combination:

means for generating a signal representative of sounds;

means for analyzing said signal representative of said sounds having an output;

means for generating a plurality of microwave signals having different frequencies having a input connected to said output of said means for analyzing said signals, having an output;

means for applying said plurality of microwave signals to the head of a subject, and

whereby the subject perceives sounds which are representative of said sounds.

3. The apparatus in accordance with claim 2 wherein said means for generating a signal is a microphone for detecting sound waves.

4. The apparatus in accordance with claim 2 wherein said means for applying said plurality of microwave signals is an antenna.

5. The apparatus in accordance with claim 4 wherein said antenna is placed in the region of the auditory cortex of the subject.

6. The apparatus in accordance with claim 2 wherein the subject is a human being.

7. The apparatus in accordance with claim 2 wherein said means for analyzing said signal comprises:

an acoustic filter bank for dividing said sounds into a plurality of component frequencies; and

a mode control matrix means for providing control signals which are weighted in accordance with said plurality of component frequencies, having an output connected to said means for generating a plurality of microwave signal inputs.

8. The apparatus in accordance with claim 7 wherein said acoustic filter bank includes a plurality of audio frequency filters.

9. The apparatus in accordance with claim 8 wherein said audio frequency filters provide a plurality of output frequencies having amplitudes which are a function of said signal representative of sounds.

10. The apparatus in accordance with claim 9 wherein said amplitudes are the weighted in accordance with transform function of the signal representative of sounds.

11. The apparatus in accordance with claim 7 wherein said mode control matrix device includes a voltage divider connected to each of said plurality of said audio frequency filters.

12. The apparatus in accordance with claim 11 wherein each of said voltage dividers has a plurality of outputs which are connected in circuit to said means for generating a plurality of microwave signals.

13. The apparatus in accordance with claim 2 wherein said means for generating a plurality of microwave signals comprises a plurality of microwave generators each having a different frequency and means for controlling the output amplitude of each of said generators.

14. The apparatus in accordance with claims 2 wherein said means for generating a plurality of microwave signals comprises a broad band microwave source and a plurality of filters.

15. The apparatus in accordance with claim 13 wherein said generators each comprise a microwave signal source and a gain controlled microwave amplifier.

16. The apparatus in accordance with claim 13 wherein said means for analyzing output is connected to said means for controlling microwave amplifier output amplitudes.

17. The apparatus in accordance with claim 13 wherein analyzing includes K audio frequency filters.

18. The apparatus in accordance with claim 17 wherein there are N microwave generators.

19. The apparatus in accordance with claim 18 including a mode partitioning means which provides N outputs for each of said K audio frequency filters.

20. The apparatus in accordance with claim 19 wherein said N amplifiers each have K inputs from said mode partitioning means.

21. The apparatus in accordance with claim 20 wherein said N amplifiers have K inputs less the mode partitioning means outputs which are so small that they may be omitted.

22. The apparatus in accordance with claim 20 wherein said mode partitioning output device outputs each include a diode connected to each microwave amplifier gain control to provide isolation between all outputs.

23. The apparatus in accordance with claim 20 wherein said K audio frequency filters are chosen to correspond to the critical bandwidths of the human ear.

24. The apparatus in accordance with claim 20 wherein said N microwave generators are each adjustable in frequency output.

25. The apparatus in accordance with claim 18 wherein the frequency of each N microwave generators is determined by anatomical estimation.

26. The apparatus in accordance with claim 18 wherein the frequency of the lowest frequency microwave generator is chosen by determination of the effect of external microwave generation on the EEG of the subject.

27. The apparatus in accordance with claim 18 wherein the frequency of each of said N microwave generators corresponds to the subject's microwave modal frequencies.

17

28. The apparatus in accordance with claim 27 wherein the subject's modal frequencies are determined by measurement of the subject's cephalic index and the lateral dimensions of the skull.

29. The apparatus in accordance with claim 28 wherein the subject's lowest modal frequency is determined by varying the frequency of the lowest frequency microwave generator about the estimated value until a maximum acoustic perception is obtained by the subject.

[57] **ABSTRACT**

Apparatus for and method of sensing brain waves at a position remote from a subject whereby electromagnetic signals of different frequencies are simultaneously transmitted to the brain of the subject in which the signals interfere with one another to yield a waveform which is modulated by the subject's brain waves. The interference waveform which is representative of the brain wave activity is re-transmitted by the brain to a receiver where it is demodulated and amplified. The demodulated waveform is then displayed for visual viewing and routed to a computer for further processing and analysis. The demodulated waveform also can be used to produce a compensating signal which is transmitted back to the brain to effect a desired change in electrical activity therein.

APPARATUS AND METHOD FOR REMOTELY MONITORING AND ALTERING BRAIN WAVES

BACKGROUND OF THE INVENTION

Medical science has found brain waves to be a useful barometer of organic functions. Measurements of electrical activity in the brain have been instrumental in detecting physical and psychic disorder, measuring stress, determining sleep patterns, and monitoring body metabolism.

The present art for measurement of brain waves employs electroencephalographs including probes with sensors which are attached to the skull of the subject under study at points proximate to the regions of the brain being monitored. Electrical contact between the sensors and apparatus employed to process the detected brain waves is maintained by a plurality of wires extending from the sensors to the apparatus. The necessity for physically attaching the measuring apparatus to the subject imposes several limitations on the measurement process. The subject may experience discomfort, particulary if the measurements are to be made over extended periods of time. His bodily movements are restricted and he is generally confined to the immediate vicinity of the measuring apparatus. Furthermore, measurements cannot be made while the subject is conscious without his awareness. The comprehensiveness of the measurements is also limited since the finite number of probes employed to monitor local regions of brain wave activity do not permit observation of the total brain wave profile in a single test.

SUMMARY OF THE INVENTION

The present invention relates to apparatus and a method for monitoring brain waves wherein all components of the apparatus employed are remote from the test subject. More specifically, high frequency transmitters are operated to radiate electromagnetic energy of different frequencies through antennas which are capable of scanning the entire brain of the test subject or any desired region thereof. The signals of different frequencies penetrate the skull of the subject and impinge upon the brain where they mix to yield an interference wave modulated by radiations from the brain's natural electrical activity. The modulated interference wave is re-transmitted by the brain and received by an antenna at a remote station where it is demodulated, and processed to provide a profile of the suject's brain waves. In addition to passively monitoring his brain waves, the subject's neurological processes may be affected by transmitting to his brain, through a transmitter, compensating signals. The latter signals can be derived from the received and processed brain waves.

OBJECTS OF THE INVENTION

It is therefore an object of the invention to remotely monitor electrical activity in the entire brain or selected local regions thereof with a single measurement.

Another object is the monitoring of a subject's brain wave activity through transmission and reception of electromagnetic waves.

Still another object is to monitor brain wave activity from a position remote from the subject.

A further object is to provide a method and apparatus for affecting brain wave activity by transmitting electromagnetic signals thereto.

DESCRIPTION OF THE DRAWINGS

Other and further objects of the invention will appear from the following description and the accompanying drawings, which form part of the instant specification and which are to be read in conjunction therewith, and in which like reference numerals are used to indicate like parts in the various views;

FIG. 1 is a block diagram showing the interconnection of the components of the apparatus of the invention;

FIG. 2 is a block diagram showing signal flow in one embodiment of the apparatus.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring to the drawings, specifically FIG. 1, a high frequency transmitter 2 produces and supplies two electromagnetic wave signals through suitable coupling means 14 to an antenna 4. The signals are directed by the antenna 4 to the skull 6 of the subject 8 being examined. The two signals from the antenna 4, which travel independently, penetrate the skull 6 and impinge upon the tissue of the brain 10.

Within the tissue of the brain 10, the signals combine, much in the manner of a conventional mixing process technique, with each section of the brain having a different modulating action. The resulting waveform of the two signals has its greatest amplitude when the two signals are in phase and thus reinforcing one another. When the signals are exactly 180° out of phase the combination produces a resultant waveform of minimum amplitude. If the amplitudes of the two signals transmitted to the subject are maintained at identical levels, the resultant interference waveform, absent influences of external radiation, may be expected to assume zero intensity when maximum interference occurs, the number of such points being equal to the difference in frequencies of the incident signals. However, interference by radiation from electrical activity within the brain 10 causes the waveform resulting from interference of the two transmitted signals to vary from the expected result, i.e., the interference waveform is modulated by the brain waves. It is believed that this is due to the fact that brain waves produce electric charges each of which has a component of electromagnetic radiation associated with it. The electromagnetic radiation produced by the brain waves in turn reacts with the signals transmitted to the brain from the external source.

The modulated interference waveform is re-transmitted from the brain 10, back through the skull 6. A quantity of energy is re-transmitted sufficient to enable it to be picked up by the antenna 4. This can be controlled, within limits, by adjusting the absolute and relative intensities of the signals, originally transmitted to the brain. Of course, the level of the transmitted energy should be kept below that which may be harmful to the subject.

The antenna passes the received signal to a receiver 12 through the antenna electronics 14. Within the receiver the wave is amplified by conventional RF amplifiers 16 and demodulated by conventional detector and modulator electronics 18. The demodulated wave, representing the intra-brain electrical activity, is amplified by amplifiers 20 and the resulting information in electronic form is stored in buffer circuitry 22. From the buffers 22 the information is fed to a suitable visual display 24, for example one employing a cathode ray tube, light emitting diodes, liquid crystals, or a mechanical plotter. The information may also be channeled to a computer 26 for further processing and analysis with the output of the computer displayed by heretofore mentioned suitable means.

In addition to channeling its information to display devices 24, the computer 26 can also produce signals to control an auxiliary transmitter 28. Transmitter 28 is used to produce a compensating signal which is transmitted to the brain 10 of the subject 8 by the antenna 4. In a preferred embodiment of the invention, the compensating signal is derived as a function of the received brain wave signals, although it can be produced separately. The compensating signals affect electrical activity within the brain 10.

Various configurations of suitable apparatus and electronic circuitry may be utilized to form the system generally shown in FIG. 1 and one of the many possible configurations is illustrated in FIG. 2. In the example shown therein, two signals, one of 100 MHz and the other of 210 MHz are transmitted simultaneously and combine in the brain 10 to form a resultant wave of frequency equal to the difference in frequencies of the incident signals, i.e., 110 MHz. The sum of the two incident frequencies is also available, but is discarded in subsequent filtering. The 100 MHz signal is obtained at the output 37 of an RF power divider 34 into which a 100 MHz signal generated by an oscillator 30 is injected. The oscillator 30 is of a conventional type employing either crystals for fixed frequency circuits or a tunable circuit set to oscillate at 100 MHz. It can be a pulse generator, square wave generator or sinusoidal wave generator. The RF power divider can be any conventional VHF, UHF or SHF frequency range device constructed to provide, at each of three outputs, a signal identical in frequency to that applied to its input.

The 210 MHz signal is derived from the same 100 MHz oscillator 30 and RF power divider 34 as the 100 MHz signal, operating in concert with a frequency doubler 36 and 10 MHz oscillator 32. The frequency doubler can be any conventional device which provides at its output a signal with frequency equal to twice the frequency of a signal applied at its input. The 10 MHz oscillator can also be of conventional type similar to the 100 MHz oscillator herebefore described. A 100 MHz signal from the output 39 of the RF power divider 34 is fed through the frequency doubler 36 and the resulting 200 MHz signal is applied to a mixer 40. The mixer 40 can be any conventional VHF, UHF or SHF frequency range device capable of accepting two input signals of differing frequencies and providing two output signals with frequencies equal to the sum and difference in frequencies respectively of the input signals. A 10 MHz signal from the oscillator 32 is also applied to the mixer 40. The 200 MHz signal from the doubler 36 and the 10 MHz signal from the oscillator 32 combine in the mixer 40 to form a signal with a frequency of 210 MHz equal to the sum of the frequencies of the 200 MHz and 10 MHz signals.

The 210 MHz signal is one of the signals transmitted to the brain 10 of the subject being monitored. In the arrangement shown in FIG. 2, an antenna 41 is used to transmit the 210 MHz signal and another antenna 43 is used to transmit the 100 MHz signal. Of course, a single antenna capable of operating at 100 MHz and 210 MHz frequencies may be used to transmit both signals. The scan angle, direction and rate may be controlled mechanically, e.g., by a reversing motor, or electronically, e.g., by energizing elements in the antenna in proper synchronization. Thus, the antenna(s) can be of either fixed or rotary conventional types.

A second 100 MHz signal derived from output terminal 37 of the three-way power divider 34 is applied to a circulator 38 and emerges therefrom with a desired phase shift. The circulator 38 can be of any conventional type wherein a signal applied to an input port emerges from an output port with an appropriate phase shift. The 100 MHz signal is then transmitted to the brain 10 of the subject being monitored via the antenna 43 as the second component of the dual signal transmission. The antenna 43 can be of conventional type similar to antenna 41 herebefore described. As previously noted, these two antennas may be combined in a single unit.

The transmitted 100 and 210 MHz signal components mix within the tissue in the brain 10 and interfere with one another yielding a signal of a frequency of 110 MHz, the difference in frequencies of the two incident components, modulated by electromagnetic emissions from the brain, i.e., the brain wave activity being monitored. This modulated 110 MHz signal is radiated into space.

The 110 MHz signal, modulated by brain wave activity, is picked up by an antenna 45 and channeled back through the circulator 38 where it undergoes an appropriate phase shift. The circulator 38 isolates the transmitted signals from the received signal. Any suitable diplexer or duplexer can be used. The antenna 45 can be of conventional type similar to antennas 41 and 43. It can be combined with them in a single unit or it can be separate. The received modulated 110 MHz signal is then applied to a band pass filter 42, to eliminate undesirable harmonics and extraneous noise, and the filtered 110 MHz signal is inserted into a mixer 44 into which has also been introduced a component of the 100 MHz signal from the source 30 distributed by the RF power divider 34. The filter 42 can be any conventional band pass filter. The mixer 44 may also be of conventional type similar to the mixer 40 herebefore described.

The 100 MHz and 110 MHz signals combine in the mixer 44 to yield a signal of frequency equal to the difference in frequencies of the two component signals, i.e., 10 MHz still modulated by the monitored brain wave activity. The 10 MHz signal is amplified in an IF amplifier 46 and channeled to a demodulator 48. The IF amplifier and demodulator 48 can both be of conventional types. The type of demodulator selected will depend on the characteristics of the signals transmitted to and received from the brain, and the information desired to be obtained. The brain may modulate the amplitude, frequency and/or phase of the interference waveform. Certain of these parameters will be more sensitive to corresponding brain wave characteristics than others. Selection of amplitude, frequency or phase demodulation means is governed by the choice of brain wave characteristic to be monitored. If desired, several different types of demodulators can be provided and used alternately or at the same time.

The demodulated signal which is representative of the monitored brain wave activity is passed through audio amplifiers 50 *a*, *b*, *c* which may be of conventional type where it is amplified and routed to displays 58 *a*, *b*, *c* and a computer 60. The displays 58 *a*, *b*, *c* present the raw brain wave signals from the amplifiers

50 *a, b, c*. The computer **60** processes the amplified brain wave signals to derive information suitable for viewing, e.g., by suppressing, compressing, or expanding elements thereof, or combining them with other information-bearing signals and presents that information on a display **62**. The displays can be conventional ones such as the types herebefore mentioned employing electronic visual displays or mechanical plotters **58***b*. The computer can also be of conventional type, either analog or digital, or a hybrid.

A profile of the entire brain wave emission pattern may be monitored or select areas of the brain may be observed in a single measurement simply by altering the scan angle and direction of the antennas. There is no physical contact between the subject and the monitoring apparatus. The computer **60** also can determine a compensating waveform for transmission to the brain **10** to alter the natural brain waves in a desired fashion. The closed loop compensating system permits instantaneous and continuous modification of the brain wave response pattern.

In performing the brain wave pattern modification function, the computer **60** can be furnished with an external standard signal from a source **70** representative of brain wave activity associated with a desired nuerological response. The region of the brain responsible for the response is monitored and the received signal, indicative of the brain wave activity therein, is compared with the standard signal. The computer **60** is programmed to determine a compensating signal, responsive to the difference between the standard signal and received signal. The compensating signal, when transmitted to the monitored region of the brain, modulates the natural brain wave activity therein toward a reproduction of the standard signal, thereby changing the neurological response of the subject.

The computer **60** controls an auxiliary transmitter **64** which transmits the compensating signal to the brain **10** of the subject via an antenna **66**. The transmitter **64** is of the high frequency type commonly used in radar applications. The antenna **66** can be similar to antennas **41, 43** and **45** and can be combined with them. Through these means, brain wave activity may be altered and deviations from a desired norm may be compensated. Brain waves may be monitored and control signals transmitted to the brain from a remote station.

It is to be noted that the configuration described is one of many possibilities which may be formulated without departing from the spirit of my invention. The transmitters can be monostratic or bistatic. They also can be single, dual, or multiple frequency devices. The transmitted signal can be continuous wave, pulse, FM, or any combination of these as well as other transmission forms. Typical operating frequencies for the transmitters range from 1 MHz to 40 GHz but may be altered to suit the particular function being monitored and the characteristics of the specific subject.

The individual components of the system for monitoring and controlling brain wave activity may be of conventional type commonly employed in radar systems.

Various subassemblies of the brain wave monitoring and control apparatus may be added, substituted or combined. Thus, separate antennas or a single multimode antenna may be used for transmission and reception. Additional displays and computers may be added to present and analyze select components of the monitored brain waves.

Modulation of the interference signal retransmitted by the brain may be of amplitude, frequency and/or phase. Appropriate demodulators may be used to decipher the subject's brain activity and select components of his brain waves may be analyzed by computer to determine his mental state and monitor his thought processes.

As will be appreciated by those familiar with the art, apparatus and method of the subject invention has numerous uses. Persons in critical positions such as drivers and pilots can be continuously monitored with provision for activation of an emergency device in the event of human failure. Seizures, sleepiness and dreaming can be detected. Bodily functions such as pulse rate, heartbeat reqularity and others also can be monitored and occurrences of hallucinations can be detected. The system also permits medical diagnoses of patients, inaccessible to physicians, from remote stations.

What is claimed is:

1. Brain wave monitoring apparatus comprising
   means for producing a base frequency signal,
   means for producing a first signal having a frequency related to that of the base frequency and at a predetermined phase related thereto,
   means for transmitting both said base frequency and said first signals to the brain of the subject being monitored,
   means for receiving a second signal transmitted by the brain of the subject being monitored in response to both said base frequency and said first signals,
   mixing means for producing from said base frequency signal and said received second signal a response signal having a frequency related to that of the base frequency, and
   means for interpreting said response signal.

2. Apparatus as in claim 1 where said receiving means comprises
   means for isolating the transmitted signals from the received second signals.

3. Apparatus as in claim 2 further comprising a band pass filter with an input connected to said isolating means and an output connected to said mixing means.

4. Apparatus as in claim 1 further comprising means for amplifying said response signal.

5. Apparatus as in claim 4 further comprising means for demodulating said amplified response signal.

6. Apparatus as in claim 5 further comprising interpreting means connected to the output of said demodulator means.

7. Apparatus according to claim 1 further comprising
   means for producing an electromagnetic wave control signal dependent on said response signal, and
   means for transmitting said control signal to the brain of said subject.

8. Apparatus as in claim 7 wherein said transmitting means comprises means for directing the electromagnetic wave control signal to a predetermined part of the brain.

9. A process for monitoring brain wave activity of a subject comprising the steps of
   transmitting at least two electromagnetic energy signals of different frequencies to the brain of the subject being monitored,
   receiving an electromagnetic energy signal resulting from the mixing of said two signals in the brain modulated by the brain wave activity and retrans-

mitted by the brain in response to said transmitted energy signals, and,

interpreting said received signal.

10. A process as in claim 9 further comprising the step of transmitting a further electromagnetic wave signal to the brain to vary the brain wave activity.

11. A process as in claim 10 wherein the step of transmitting the further signals comprises

obtaining a standard signal,

comparing said received electromagnetic energy signals with said standard signal,

producing a compensating signal corresponding to the comparison between said received electrogagnetic energy signals and the standard signal, and

transmitting the compensating signals to the brain of the subject being monitored.

[57] ABSTRACT

A biomagnetic analytical system for sensing and indicating minute magnetic fields emanating from the brain or from any other tissue region of interest in a subject under study. The system includes a magnetic pick-up device constituted by an array of fiber-optic magnetic sensors mounted at positions distributed throughout the inner confines of a magnetic shield configured to conform generally to the head of the subject or whatever other body region is of interest. Each sensor yields a light beam whose phase or other parameter is modulated in accordance with the magnetic field emanating from the related site in the region. The modulated beam from each sensor is compared in an interferometer with a reference light beam to yield an output signal that is a function of the magnetic field being emitted at the related site. The output signals from the interferometer are processed to provide a display or recording exhibiting the pattern or map of magnetic fields resulting from emanations at the multitude of sites encompassed by the region.

BIOMAGNETIC ANALYTICAL SYSTEM USING FIBER-OPTIC MAGNETIC SENSORS

BACKGROUND OF INVENTION

1. Field of Invention

This invention relates generally to biomagnetic analytic systems for sensing and indicating minute magnetic fields emanating from the brain and other tissue regions of the human body, and more particularly to a system using fiber-optic magnetic sensor pick-up devices for this purpose.

2. Status of Prior Art

Biomagnetic fields arise from three principal sources, the first being electric currents produced by the movement of ions. The second source is remanent magnetic movement of contaminants, and the third is paramagnetic or diamagnetic constituents of the body.

The first source is of primary significance in human brain activity in which the currents creating the magnetic fields result from signals generated by neurons as they communicate with each other and with sensory organs of the body. The intensity of extracranial magnetic field produced by such currents is extremely minute, having a strength no more than about a billionth of the magnetic field at the earth's surface. It is usually measured in terms of tesla (T) or gauss (G), one T being equal to 10^4 G.

The magnetic field arising from spontaneous brain activity (alpha waves) is about one picotesla (IpT$=10^{-12}$T), whereas the magnetic field at the earth's surface is about 6×10^{-5}T. The magnetic field emanating from the brain has a strength much below that emitted by the heart. Hence monitoring of brain magnetic activity presents formidable difficulties.

A major concern of the present invention is magnetoencephalography (also commonly referred to as MEG). This is the recording of magnetic fields emanating from the brain resulting from neuronal electric currents, as distinguished from an electroencephalogram (EEG) in which electric potentials originating in the brain are recorded. With an EEG measurement, it is difficult to extract the three-dimensional distribution of electrically active brain sites from potentials developed at the scalp. While this difficulty can be overcome by inserting electrodes through apertures bored in the skull, this invasive technique is not feasible in the study of normal brain functions or to diagnose functional brain disorders or brain dysfunctions. Thus ionic currents associated with the production of electrically measurable epileptic seizures generate detectable extracranial magnetic fields, and these can be detected externally without invading the skull.

Non-invasive MEG procedures are currently used in epilepsy research to detect the magnetic field distribution over the surface of the head of a patient with a view to localizing the seizure foci and spread patterns. This analysis serves as a guide to surgical intervention for the control of intractable seizures. (See: "Magnetoencephalography and Epilepsy Research"—Rose et al.; Science—16 Oct. 1987—Volume 238, pp. 329-335.)

MEG procedures have been considered as a means to determine the origin of Parkinson's tremor, to differentiate at the earliest possible stage Alzheimer's disease from other dementias, and to localize the responsible cortical lesions in visual defects of neurological origin. MEG procedures are also of value in classifying active drugs in respect to their effects on specific brain structures, and to in this way predict their pharmaceutical efficacy. And with MEG, one can gain a better understanding of the recovery process in head trauma and strokes by observing the restoration of neurological functions at the affected site.

But while MEG holds great promise in the above-noted clinical and pharmaceutical applications, practical considerations, mainly centered on limitations inherent in magnetic sensors presently available for this purpose, have to a large degree inhibited these applications.

The characteristics of biomagnetic activity that are measurable are the strength of the field, the frequency domain and the nature of the field pattern outside of the body. In magnetoencephalography, measurement of all three of these components are important. Ideally, simultaneous measurement of three orthogonal components of the magnetic field provides a complete description of the field as a function of space and time. Coincident measurement of the magnetic field along the surface of the skull can provide a magnetic field map of the cortical and subcortical magnetic activity. With spontaneous activity, the brain emits magnetic fields of about 10^{-8} to 10^{-9} Gauss, compared with approximately 10^{-6} Gauss emitted by the heart. Thus, monitoring of the brain's magnetic activity places heavy demand upon the required hardware.

In brain activity, the current dipole or source is generated by the current flow associated within a neuron or group of neurons. Volume current is analogous to the extracellular component of the current source. In MEG, the net magnetic field measured depends on the magnetic field generated by the current dipole itself. The contribution from volume conduction is small in which approximations to spherical symmetry are made. However, there are tangential magnetic components originating from secondary sources representing perturbations of the pattern by the volume current at boundaries between regions of different conductivity. Contributions from these secondary sources to the tangential component of the field become relatively more pronounced with distance from the current dipole. But there is no interference from these secondary sources when measurement is confined to the magnetic fields perpendicular to the skull.

In biomagnetic analysis, three types of magnetic sensors are known to have adequate sensitivy and discrimination against ambient noise for this purpose. (See: "Magnetoencephalography"—Sato et al.—Journal of Clinical Neurophysiology—Vol. 2, No. 2—1985.) The first is the induction coil. But because of Nyquist noise associated with the resistance of the windings and its loss of sensitivity at frequencies below a few Herz, the induction coil is rarely used in MEG studies.

The second is the Fluxgate magnetometer; and while this has been used in geophysical studies, it has certain drawbacks when used in MEG applications. It is for this reason that the third type, the SQUID system, is presently used almost exclusively in MEG applications.

A SQUID (Superconducting QUantum Interference Device) comprises a superconducting loop incorporating a "weak link" highly sensitive to the magnetic field encompassed within the area of the loop. While the loop itself can act as a magnetic field sensor, use is made of a detection coil tightly coupled to the superconducting loop, the coil acting as a flux transformer. Both the coil and the loop are immersed in a bath of liquid helium contained within a dewar.

With the advent of so-called high-temperature superconductors operating at liquid nitrogen temperatures, a SQUID magnetometer has been developed using such superconductors. (See: "The Impact of High Temperature Superconductivity on SQUID Magnetometers"—Clarke et al.—Science—Vol. 242—14 Oct. 1988.)

In the booklet published by Biomagnetic Technologies, Inc., of San Diego, Calif., entitled "Introduction to Magnetoencephalography—A New Window on The Brain," there is disclosed a SQUID-type sensor for MEG studies. This SQUID is especially suited to measure magnetic fields in the frequency range from DC to 20 kHz, the magnetic field being converted into a signal that is amplified, filtered and displayed for subsequent analysis.

Because the brain's field falls off sharply with distance from the head, the dewar for the cryogenic liquid, which is inherently bulky, is provided with a tail section of reduced diameter to house the pick-up coil and to minimize the distance of the coil from the head of the patient being studied, thereby maximizing the detected field.

As pointed out in the above-identified booklet, in order to produce a contour map of the brain, the magnetic field must be measured simultaneously at a number of points outside the head. While it is possible with SQUIDS to sample the magnetic field emanating from the brain at one to seven points separated laterally from each other by several centimeters, a complete mapping of the field pattern at a given instant requires forty or more pick-up points. It is proposed, therefore, in the booklet to move SQUID sensors from one point to another to accumulate the required field data. But a measurement taken at a point X will not reveal magnetic brain activity taking place concurrently at a point Y if one has to physically shift the sensor from point X to point Y.

The booklet notes that the ultimate goal of MEG measurement is to simultaneously observe all areas of the brain to produce real-time activity maps responding instantaneously to changes as they occur. However, the booklet concedes that this goal has not yet been realized with SQUID sensors.

The present invention attains this goal by means of fiber-optic magnetometers (FOM). In a FOM sensor, a magnetostrictive alloy is interfaced with an optical fiber to produce a magnetometer whose principle of operation is based on the transference of strain from the magnetostrictive material to the core of the optical fiber via mechanical bonding. This results in modulation of the phase or other parameters of the light propagated in the fiber which is subsequently detected by a fiber-optic interferometer. Integrated fiber-optic magnetometers in which all components are fabricated on or around the optical fibers are now known.

FOM sensors of the type currently available are far less expensive to manufacture and maintain than SQUID sensors; they are considerably more compact, and they operate at room temperature. Their sensitivity to weak magnetic fields, which can be greater than that of a SQUID, renders them suitable for MEG and other applications.

The disclosures of these publications are incorporated herein by reference.

SUMMARY OF INVENTION

In view of the foregoing, the main object of this invention is to provide a biomagnetic analytical system which includes a pick-up device employing an array of fiber-optic magnetic (FOM) sensors for measuring and indicating minute magnetic fields emanating from a multitude of sites in the brain or in other tissue regions of interest in a subject being diagnosed.

A significant advantage of a fiber-optic magnetic sensor (FOM) over a SQUID is that the former is a solid-state device that is considerably smaller than the latter and requires no cryogenics, thereby making it possible to distribute a multitude of the sensors (i.e., in excess of forty) around the skull of the patient or about any other tissue region of interest to effect more accurate localization of magnetic activity, as well as a more precise determination of the physiological condition of the region being studied.

More particularly, an object of this invention is to provide a system of the above type for MEG analysis in which the FOM sensors are so distributed in a three-dimensional array as to pick up magnetic fields emanating from a multitude of brain sites simultaneously and to spatially localize the field signals.

Also an object of the invention is to provide a shielded magnetic pick-up device in which the FOM sensors in the array are magnetically shielded from each other to prevent magnetic interaction therebetween, as well as from magnetic fields extraneous to the region of interest, thereby obviating the need for a shielded room to conduct studies on biomagnetic activity.

Yet another object of the invention is to provide a biomagnetic system in which the outputs of the FOM sensors in the array are multiplexed, whereby a common interferometer can be used for the multitude of sensors in the array thereof.

Briefly stated, these objects are attained in a biomagnetic analytical system for sensing and indicating minute magnetic fields emanating from the brain or from any other tissue region of interest in a subject under study. The system includes a magnetic pick-up device constituted by an array of fiber-optic magnetic sensors mounted at positions distributed throughout the inner confines of a magnetic shield configured to conform generally to the head of the subject or whatever other body region is of interest.

Each sensor yields a light beam whose phase or other parameter is modulated in accordance with the magnetic field emanating from the related site in the region. The modulated beam from each sensor is compared in an interferometer with a reference light beam to yield an output signal that is a function of the magnetic field being emitted at the related site. The output signals from the interferometer are processed to provide a display or recording exhibiting the pattern or map of magnetic fields resulting from emanations at the multitude of sites encompassed by the region.

BRIEF DESCRIPTION OF DRAWINGS

For a better understanding of the invention as well as other objects and further features thereof, reference is made to the following detailed description to be read in conjunction with the accompanying drawings, wherein:

FIG. 1 is a perspective view of a magnetic field pick-up device in the form of a helmet which is fitted over the head of a patient and which incorporates an array of FOM sensors for simultaneously detecting magnetic fields emanating from a multitude of sites in the brain;

FIG. 2 shows the helmet partially cut away to expose an inner insulating liner on which the sensors are mounted;

FIG. 3 is a separate view of the inner liner, illustrating the manner in which the FOM sensors are shielded from each other;

FIG. 4 illustrates, in perspective, a cylindrical magnetic pick-up device;

FIG. 5 shows a semi-cylindrical section of the pick-up device;

FIG. 6 shows a flat pick-up magnetic device;

FIG. 7 illustrates a unit for accommodating a patient undergoing a magnetoencepahlographic examination; and

FIG. 8 illustrates schematically a biomagnetic analytical system in accordance with the invention operating in conjunction with a pick-up device that is appropriate to the region being studied.

DETAILED DESCRIPTION OF INVENTION

FOM Pick-Up Devices

Referring now to FIGS. 1 to 3, there is shown one preferred embodiment of a pick-up device 10 in accordance with the invention, adapted to detect magnetic fields emanating from a multitude of sites on the brain of a patient for purposes of magnetoencelographic (MEG) examination.

Pick-up device 10 includes a generally spherical helmet 12 formed of ferromagnetic or superconductive shielding material, the helmet being configured to generally conform to the head of a patient 11 so that the brain therein lies within the confines of the helmet, and the weak magnetic fields emanating from the brain are confined within the helmet which acts to exclude extraneous magnetic fields, including those emanating from external electronic equipment associated with the pick-up device.

Helmet 12 is provided with a conforming inner liner 13 formed of electrical insulating material, such as in synthetic plastic material or an epoxy compound having good dielectric properties. Embedded in liner 13 or otherwise mounted thereon is a three-dimensional array of identical FOM sensors 14, each provided with a fiber-optic light conducting line 15 to supply light from a suitable laser beam source to the sensor and to conduct the light modulated by the sensor in response to the magnetic field detected thereby to an external interferometer. Lines 15 are bundled to form a cable 16 running from the pick-up device to external signal processing apparatus.

The FOM sensors 14 in the three-dimensional array are distributed uniformly throughout the inner confines of helmet 12, so that each sensor acts to pick up a unique magnetic field emanating from the head.

As shown in FIG. 3, FOM sensors 14 are internally shielded from each other but not from the magnetic fields emanating from the brain by an open cell ferromagnetic honeycomb 17 so that there is no magnetic interaction between the sensors.

Fiber-optic magnetometers are well known, as evidenced by references (1) to (4), supra. The operation of FOM sensor is based on the transference of strain from the magnetostrictive material in response to a magnetic field to the core of the optical fiber via mechanical bonding, resulting in a phase modification of the propagated light beam. The modulated light from the sensor is subsequently processed in an interferometer which may take the form of a photodetector which compares the phase-modulated light beam with a reference light beam to provide an output signal that is a function of the phase displacement caused by the magnetic field to which the sensor is exposed.

FOM sensors are available in various configurations. In one such configuration, the optical fiber is bonded to a magnetostrictive element to form a waveguide strip that is then coiled into a spool so that the entire sensor is very small. For alternating-current measurements using, for example, metallic glasses as the sensing material, magnetic sensitivities of the order of 10^{-9} G/m of fiber core are obtainable.

Design improvements such as magnetic feedback nulling (Reference 4) can lead to improvements in the linear dynamic range, high suppression of magnetic hysteresis associated with the magnetic material, and improved long-term stability. Methods of improving fluctuations of the transmission characteristics of the fiber (induced by the surrounding environment) exist such as use of phase-sensitive transducers combined with a single polarization-maintaining fiber. Thus polarization-rotated reflection can be used to enhance the performance of the system.

Of the many configurations the magnetometer can take, all detect an externally-induced optical phase shift. The sensitivity of the system is proportional to the length of the fiber, until such time as the length approaches the point where other optical properties of the fiber interfere with the propagation of light. The measurement of the linear strain in length of the fiber which is bonded to (or coated by) the magnetostrictive material forms part of one arm of a fiber interferometer. Several types of interferometer designs have been employed, among which are the Fabra Perot, Mach Zender, Michelson and Sagnac types. Well designed interferometers can detect induced optical phase shifts below $10^{31\,6}$ rad over the frequency range of 10–10^{4} Hz. Thus, very weak magnetic fields per meter of fiber can be detected.

The sensor configuration can be a fiber bonded to a magnetostrictive tube or mandrel, a metal film deposited on the fiber, a metallic glass strip bonded to fibers or a metallic glass cylinder. The magnetic materials which are sensitive in the range of DC to 50 kHz are nickel, iron-nickel alloys, cobalt-nickel, and metallic glasses. Piezoelectric activity in the jacket of the fiber can be achieved by the use of various types of polymer films.

Sensing of small AC magnetic fields at optimal DC
etic fields for various frequencies can occur.
easuring technique enables the separation of
ic effect (at relatively higher frequencies)

31

from environmental effects (such as temperature or acoustics at lower frequencies) on the fiber interferometer. Thus, the fiber interferometer can be stabilized without losing sensitivity to magnetic fields.

To extend the AC measuring technique to measure DC bias magnetic fields, one can make use of the effect of DC bias magnetic fields to change the interferometer output due to a fixed AC magnetic field drive at a given frequency. In a sense, this technique utilizes an AC approach to measure DC magnetic fields, thereby overcoming both the environmental perturbation and the 1/f noise problem usually associated with low frequency measurements. It is the nonlinear response of the magnetostrictive material that allows the utilization of an AC technique to measure DC magnetic fields.

In the helmet-type pick-up device shown in FIGS. 1 to 3 which is adapted for MEG studies, each FOM sensor 14 in the three-dimensional array thereof is oriented so that the longitudinal axis of the optical waveguide coil or spool is substantially perpendicular to the surface of the skull of patient 11 wearing the helmet. This orientation makes it possible to dispose a multitude of sensors (forty or more) at positions distributed uniformly about the skull. The density of the coils in the array is limited by factors such as the physical diameter of each spool and induced noise from nearby spools such as eddy currents.

In biomagnetic measurements, sensitivity is limited by fluctuations in the ambient fields and not the intrinsic noise of the sensor. Such ambient fields are produced primarily by the sensor itself, motorized machinery and metallic structural components of buildings which distort the earth's geomagnetic field. The earth's geomagnetic field is uniform and steady. The problem arises when a sensing system vibrates, often in the 1–10 Hz range. Also, the subject may produce noise from normal physiological activity. In MEG, the head proper is the source of a significant amount of noise, produced primarily by the cortex. But because the array of sensors lies within a shield and each sensor occupies a position within a cell in a honeycomb shield, the sensors are isolated from ambient noise and magnetic interaction therebetween is prevented.

Each sensor acts as a gradiometer of predetermined order, any three of which can be used to localize biomagnetic sources at any brain site by the use of the computation techniques described hereinafter.

The pick-up device shown in FIGS. 1 to 3 is adapted to be placed over the head of a patient for MEG analysis. But in practice, the pick-up device can be customized to pick up magnetic field activity arising in other body regions of interest. Thus in measuring magnetic fields generated by the heart, the appropriate pick-up device, as shown in FIGS. 4 and 5, is in a cylindrical form composed of a pair of complementary semi-cylindrical sections 18 and 19 which are joined together by Velcro fasteners 20 or similar means which makes it possible to detach the sections from each other. In practice, for heart analysis, the cylinder is positioned around the thorax.

The cylinder is constituted by an outer shell 21 of shielding material having an inner liner 22 of insulating material in which are embedded a cylindrical array of FOM sensors 23. This cylindrical array of sensors surrounds the thorax, each sensor picking up the magnetic field emanating from a respective site in the heart.

The cylindrical pick-up device can also be configured to go around a limb to measure magnetic fields generated by the muscles therein. For other parts of the body, a flat pick-up device may be appropriate. This flat device, as shown in FIG. 6, is provided with an outer metal plate 24 of shielding material laminated to an inner block 25 of electrical insulating material in which a rectangular array of FOM sensors 26 is embedded.

In practice, the cylindrical pick-up device may be applied to any extremity; and a semi-cylindrical pick-up section can be used separately for measurement purposes. The flat pick-up device is useful for small surface measurements.

In practice, the pick-up device may be contoured to conform to any body region of interest. Thus the pick-up device can be used in a broad range of medical applications by making available to the practitioner a family of pick-up devices, each customized for a particular part of the body. The pick-up device is strapped or otherwise attached to the body part when a biomagnetic study is to be conducted.

For MEG procedures, as shown in FIG. 7, the helmet-type pick-up device 10 may be included as the headpiece of a support unit 27 which also provides a seat, a back rest and a foot platform for the patient whose head is received by the helmet. Housed in the unit is electronic equipment for processing the outputs of the FOM array contained in the helmet.

If one wishes to conduct biomagnetic studies on all portions of the body with a single pick-up device, the pick-up device for this purpose (not shown) may take the form of a sarcophagus-like magnetically shielded enclosure with suitable breathing vents, within which enclosure are disposed arrays of FOM sensors to pick up magnetic fields from different regions of the body. In practice, various standard electronic techniques can be used for noise reduction, either separately or in combination with physical shielding.

The Biomagnetic Analytical System

As shown in FIG. 8, one preferred embodiment of a biomagnetic analytical system in accordance with the invention includes a magnetic field pick-up device 28 in a configuration appropriate to the region under study. Device 28 includes an outer shield 29 within which is an array of FOM sensors 30, each coupled by a fiber-optic line 31 to the input of a multiplexer 32 whose output is applied to an interferometer 33.

Thus instead of having a separate interferometer channel for each FOM sensor which would be very costly, a common interferometer now serves sequentially to compare the modulated light beam derived from each sensor in the array with a reference light beam to produce an output signal. This output signal is a function of the sensed magnetic field emanating from the site related to the sensor.

In practice, multiplex transmission of the signals from the interferometer may be either optical or electrical; that is, by optical waveguides or by conductive wires in the case where the interferometer is of the type which applies the modulated light signal to a photodetector to be compared with the reference light beam.

The output signals from interferometer 33 representing the sensed magnetic fields is applied to a data acquisition stage 34.

The output of interferometer 33 is phase information related to the degree of phase rotation resulting from the detection of the incident vector of the magnetic field transient on the fiber optic sensor. This phase information can evolve over time as the biomagnetic

32

signal progresses, and it is of an analog nature. Therefore, it can be acquired, recorded, and processed in either the analog or digital form. For purposes of the present embodiment, reducing the data to, and processing the data in digital form will be discussed. However, the specific means of data handling is not important to the invention.

Time-varying phase information can be represented in the form of an evolving analog voltage which is proportional to the phase shift by a predetermined relationship. This signal can be converted to digital form through a conventional high speed sample-and-hold and analog-to-digital converter (ADC) means whereby the resulting bandwidth of the recorded signal can be limited to that which is determined by the sampling rate of this analog signal according to the Nyquist sampling theorem.

Since the signal from each sensor on the sensor array is time-multiplexed before entering data acquisition stage 34, a single ADC system is sufficient to digitize the signals from the entire sensor array. However, it should be noted that due to the signal bandwidth requirements and the size of the sensor array, it might be possible that the amount of data generated may result in a data rate which is high enough that the conversion rate of a single ADC might be exceeded and thus, a single ADC channel would not suffice. In this case, the multiplexed signal must then be de-multiplexed, the data from each sensor within the array then being directed to a respective ADC channel, there being one ADC channel per sensor, for example.

In practice, several electronic methods may be used to reduce noise, including the use of comb filters, subtracting a reference channel from a signal channel, adaptive filtering of analog or digital format or balancing of detectors. These can quite effectively reduce the ambient noise, even to the point where physical shielding may not be necessary.

The system lends itself to any number of data acquisition and processing means. For example, since the phase information in a magnetoencephalographic signal can be presented in optical form, the data is particularly suited to processing by optical computer technology.

The output of data acquisition stage 34 is applied to a data processing stage 35. Through the applications of standard spatial localization algorithms, such as are addressed by point source theory, a three-dimensional histogram map can be generated to represent the location and relative magnitude of each magnetic dipole source. The processing of the data will depend upon the configuration of the sensor array, since the proper 3-D mapping of the magnetic dipoles mandates a predetermined geometry of the plane of the array as well as the spacing between each sensor element within the array.

Once the data is acquired in digital form, it can be immediately processed by conventional digital computer means for the purposes of relating the data in various formats including those clinically relevant such as (a) time-varying analog and bandwidth information for each channel, and (b) the spatial localization, through the application of point source theory, of the magnetic dipoles which generated the magnetic field transients that were detected by the sensor array. The data can also be directed to a storage medium for the purpose of recording the digitized biomagnetic data for archiving and later retrieval and processing.

Additionally, other correlative modalities may be employed in conjunction with the biomagnetic data in order to obtain more complete information about a particular body tissue or system. Thus, modalities such as EEG, EKG, MRI and X-ray from a source 36 can be combined with the biomagnetic data in the data processing stage 35 and represented according to the particular need of the practitioner.

The output of data processing stage 35 is applied to a data reduction stage 37. The computational techniques necessary for resolution of the image and decoding it into a meaningful "image" for the clinician to interpret requires Fourier analysis of the affected light similar to the analyses utilized by the magnetic resonance imaging (MRI) technology. The FOM-based system in accordance with the invention allows for the detection of a large number of points simultaneously. This feature is most important, since clinicians have long sought a method of actually visualizing the physiological processes of the intact brain (especially deep brain structures) in various states of sleep and consciousness.

Two major problems encountered by the conventional SQUID-based system for MEG is that the resolution is not very good, and that the number of sensors that can be employed is quite limited, thereby limiting the sites in the brain that can be "scanned" for possible pathologies. These two cumbersome problems are overcome with the FOM-based system, making possible many more clinical applications.

With regard to the actual diagnosis of pathologies, the system is targeted toward the same professionals for whom the conventional SQUID-based system is designed. Primarily, these are radiologists, neurologists and surgeons. For example, the practitioner could "see" a functional image of the brain on a CRT, but the image will be a profile of the electromagnetically "active" portions of the brain, as shown by the magnetic pattern 38 derived from data reduction stage 37. The display plane can represent the location of each magnetic dipole source, and one pixel intensity can represent the magnetic dipole magnitude or phase with respect to a reference signal. What these active areas mean, and how they relate to pathologies is currently an area of intense interest in the basic and clinical neurosciences. Such areas of activity might signify anything from a soft-tissue pathology to abnormal behavioral patterns where no morphological or biochemical anomaly can be detected.

The format of data presentation can take the form of a static or time-varying uni- or multi-dimensional display.

Uni-dimensional display conforms to the current standards of SQUID-based magnetometry and of clinical electrophysiology. In this case, data is represented as linear time-varying representations of single detector elements. Multi-dimensional analysis can provide two- or three-dimensional graphic representations of the data. These multi-dimensional constructs are the result of applying the point source theory algorithms referred to above and can represent the dipole data spatially, or in terms of other dimensionalities, such as k-space in the Fourier domain.

Thus, the three-dimensional histogram map which can be representative of the location and relative magnitude of each magnetic dipole source can be rendered on a standard graphic workstation 39. Application-specific labelling must be applied to convey orientation and scaling of the 3-D data matrix. The display may take the graphical form 40 in which the level of each sensed field derived from the FOMs is represented by a column. Or the levels may be separately indicated on a record chart 41.

Advantages

The main advantages of the system are as follows:

I. Each FOM-based sensor is far smaller than a SQUID-based sensor. Thus, a multitude of FCM sensors can be placed over or around the region of interest by the magnetic pick-up device.

II. A system of gradiometers of predetermined order allows for a more accurate localizatior of biomagnetic activity, and a precise determination of the physiological condition.

III. The system affords more freedom to investigate several areas of the tissue region of interest simultaneously, since it provides a means to spatially localize the field signals.

IV. The biomagnetic analyzing system does not use expensive cryogens. The FOM-based pick-up device entails minimal installation time and service requirements.

V. The FOM sensor is relatively easy and inexpensive to construct, since only "solid-state" materials are required.

VI. The magnetic shielding needed for the FOM-based biomagnetic monitoring is limited to the area surrounding the region of interest, thereby eliminating the need for a specially shielded room.

VII. Even if a shielded room or enclosure is preferred for added noise reduction, the enclosure need not be larger than that required to placed the patient in comfortably.

VIII. Multiplexing the output from the sensing array makes it possible for more sensors to be monitored with fewer "decoding" devices at the "back end."

IX. The FOM-based pick-up device produces optical data that lends itself to optical computing available through the field of "photonics" involving optical processing technologies which can drastically decrease data processing times without compromising resolution.

While there has been shown and described a biomagnetic analytical system using various embodiments of FOM pick-up devices in accordance with the invention, it will be appreciated that many changes and modifications may be made therein, without, however, departing from the essential spirit thereof.

We claim:

1. A biomagnetic analytical system for sensing and indicating minute magnetic fields emanating from the brain or any other tissue region of interest in a subject being diagnosed, said system comprising:

(a) a magnetic pick-up device having an outer shell contoured to conform generally to the region of interest, said shell being formed of magnetic shielding material to exclude from its inner confines extraneous magnetic fields, whereby the emitted magnetic fields exist within the confines of the shell, and an array of fiber-optic magnetometer sensors which conforms to the contours of the shell, the sensors being mounted within the shell at positions distributed throughout the inner confines thereof, whereby each sensor is related to a site in the region and yields a light beam modulated in accordance with the magnetic field emanating from this site; and

(b) means including an interferometer to compare the modulated light beam yielded by each sensor in the array with a reference light beam to produce an output signal that is a function of the magnetic field emitted at the related site.

2. A system as set forth in claim 1, wherein said sensors are each disposed within a respective cell of a honeycomb shield supported within the shell to prevent magnetic interaction between the sensors.

3. A system as set forth in claim 1, wherein said sensors in the array are supported on an electrically insulating inner liner conforming to the inner contours of the shell.

4. A system as set forth in claim 1, wherein said shell is configured as a helmet to be worn by the subject for brain magnetic field diagnosis.

5. A system as set forth in claim 1, wherein said shell is configured as a cylinder for heart magnetic field diagnosis.

6. A system as set forth in claim 1, further including means coupled to the output of said interferometer to process the output signals from the interferometer to provide a display exhibiting the pattern of magnetic fields emanating from the sites encompassed by the region.

7. A system as set forth in claim 1, wherein said array has at least forty sensors.

8. A system as set forth in claim 1, wherein the modulated light beams from the sensors are applied sequentially to the interferometer through a multiplexer.

[57] ABSTRACT

Topographic displays of brain electrical activity are produced from matrices of data derived from evoked potential (EP) and steady-state responses of skull transducers. In different aspects, EP responses are displayed at a variable frame rate, the rate of data sampling is sufficient to capture rapid transient events, difference matrices are derived as the difference between matrices corresponding to two different brain conditions, the baseline of the EP responses is zeroed based on the average prestimulus response, and the steady-state response is analyzed by Fourier transforms. In other aspects, statistical comparison matrices representing statistical differences between corresponding elements in two matrices are generated, a coefficient-of-variance matrix is generated, additional display matrices are temporally interpolated, response waveforms are previewed and tagged for elimination from further processing, the topographic maps are displayed on a video monitor with appropriate scaling of the data to the tones of the display, and additional display points are interpolated between the measured data points for display.

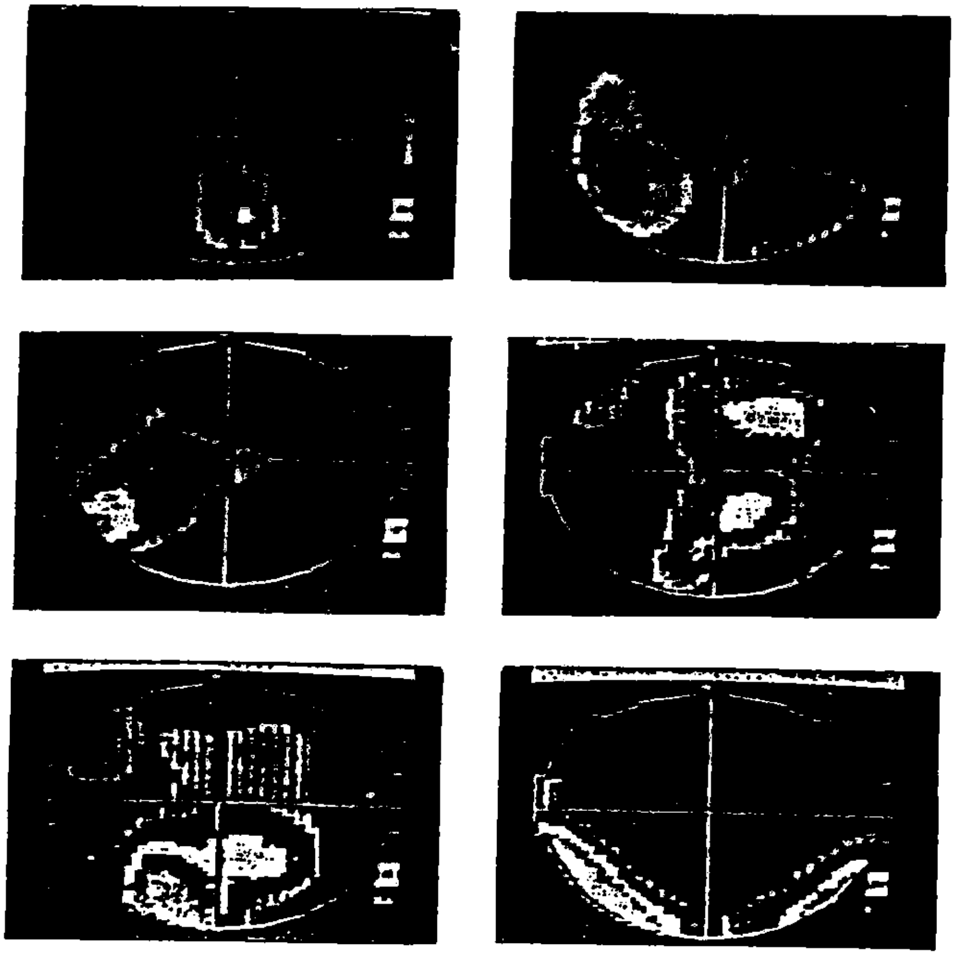

FIG. 32

BRAIN ELECTRICAL ACTIVITY MAPPING

The invention described herein was made in the course of work under a grant or award from the Department of Health and Human Services.

BACKGROUND OF THE INVENTION

This invention relates to analysis of brain electrical activity and diagnosis of brain disorders.

Traditional electro-encephalographic (EEG) techniques of analyzing brain electrical activity to diagnose brain dysfunction require the skilled neurophysiologist to observe and distinguish time and frequency related characteristics of many channels of voltage waveforms derived from an individual's brain and to determine, largely from memory, differences between that individual's waveforms and waveforms characteristic of a normalized population. The process necessarily fails to take account of many subtle but potentially useful pieces of information contained in the analyzed data.

Signal averaged sensory evoked potential (EP) transient responses have also been used as a source for brain electrical activity analysis, but large amounts of useful information contained in such transient response waveforms have traditionally been disregarded because of the difficulty of visualizing the inter-relationship over time of many channels of such information.

SUMMARY OF THE INVENTION

The invention features, in one aspect, displaying time sequences of topographic maps at a variable frame rate. In preferred embodiments, the rate can be selected to display protions of the EP response immediately following the stimulus at a slower rate than later portions; and in preferred embodiments the rate can be varied logarithmically. The variation of display rate permits the operator to give more emphasis to matrices which contain relatively more information, such as the earlier EP response matrices.

In another aspect, the invention features generating topographic displays of information on electrical activity of the brain produced at a plurality of transducers on the skull; generating a time sequence of matrices of electrical activity at successive points in time sufficient in number to capture the onset of a rapid transient event; and displaying the matrices as topographic maps in time sequence at a variable rate. In preferred embodiments, the processor is capable of generating 200 or more matrices for each second of real time. The ability to capture a large number of matrices in a short period of time permits the observation of short-term events such as epileptic spikes.

In another aspect, the invention features generating topographic displays of information on brain electrical activity produced at a plurality of skull transducers; storing the electrical activity of such transducers for two different brain conditions; generating matrices of elements representing electrical activity in the two conditions; forming a difference matrix between corresponding elements of the two matrices; and displaying the difference matrix as a topographic map. In preferred embodiments, the two brain conditions are attained by the use of a patterned light stimulus and a non-patterned light stimulus. The ability to form and display difference matrix enables the operator to identify parts of the brain involved in particular brain states or evoked responses.

In another aspect, the invention features generating topographic displays of information on brain electrical activity produced at a plurality of skull transducers; repeatedly triggering EP responses at the transducers, including pre-stimulus and post-stimulus responses; averaging the responses; setting as a baseline the mean level of the pre-stimulus response; generating matrices from such responses; and displaying topographic maps of the matrices. In preferred embodiments the time of occurrence of each stimulus is stored and the response is divided into pre-stimulus and post-stimulus periods; the matrices generated are a set of time-sequenced frames during the response and are displayed as a sequence of topographic maps; the sequence can be displayed as an endless sequence of maps; the averaging process can be performed using digital words added into summing buffers; and the sampling, storing, response averaging, baseline calculation and subtraction can all be performed digitally; averaging of the pre-stimulus baseline can exclude selected portions of the response; the response can be reviewed to determine the appropriateness of the baseline; there can be calculated the V_{RMS} of the average pre-stimulus and post-stimulus responses and the V_{RMS} can be displayed with the responses, so that the user can determine whether the noise level for any transducer is unacceptably large; the operator can manually adjust the baseline up or down; high-frequency components can be filtered from the post-stimulus response by multipoint interpolation; and the baseline calculation can be repeated until the results are satisfactory. In general, these various features permit the operator to assemble, modify and adjust to an accurate zero level a set of EP responses so that the ultimate topographic display will be accurate and useful. The display of a time-sequence of frames permits the operator to visualize the movement of brain activity in the course of an EP response over the skull. The proper setting at the baseline improves the utility of each response when used in a topographic display, since the relative levels of response at different transducers is more accurately portrayed.

In another aspect, the invention features filtering to remove from the EEG responses frequency components outside the prominent frequency bands of electrical activity; determining, for each transducer, the Fourier transforms and the spectral energy in selected frequency bands, during a period when the brain activity remains in the same state; and processing the results into display matrices for the selected frequency bands. In preferred embodiments, the brain activity can be sampled, stored and Fourier transformed digitally; the filters can remove frequency components below 0.5 Hz and about 50 Hz; the samples can be taken at least 3 times as frequently as the highest frequency in the prominent frequency bands, and particularly at 4 to 5 times that highest frequency; the Fourier analysis can be limited to a period between marked starting and stopping points; the period during which electrical activity is sampled can be limited to avoid interruptions in the subject's brain state, and particularly can be limited to two second sampling periods; the number of samples can be between 20 and 2000; and the frequency bands analyzed can comprise the alpha, beta, delta and theta bands. Removal of irrelevant frequency bands, sampling at high rate, and limiting the sampling period all enable the operator to obtain accurate spectral analyses with minimum interference. The ability to analyze specific frequency bands of interest enables the operator to review information which effectively corresponds to the electrical activity of the brain in various states.

In another aspect, the invention also features generating a statistical comparison matrix from two matrices, each element of the statistical comparison matrix representing a statistical difference between the corresponding elements in the two matrices; and displaying the statistical comparison matrix as a topographic map. In preferred embodiments, the statistical comparison matrix can be interpolated into a display matrix having additional display points; the statistical comparison can be made between two expanded matrices rather than between two unexpanded matrices; the statistical comparison can be a t-statistic analysis, or a z-statistic analysis; and quantitative features useful for diagnosis can be determined from regions of the maps. The ability to perform and topographically display statistical differences between groups and between an individual and a group offers a versatile and effective tool for visualizing brain areas which are connected to particular brain dysfunctions or to particular brain activities, and for neurophysiological diagnosis and research.

In another aspect, the invention also features generating a coefficient-of-variance matrix, each element of which represents the normalized standard deviation at one skull location; and displaying the coefficient-of-variance as a topographic map.

In another aspect, the invention also features temporally interpolating matrices which represent the response at time instants between other matrices; and displaying said interpolated matrices. The temporal interpolation provides a smoother visual transition between the original frames when a time-sequenced display is presented.

In another aspect, the invention also features previewing waveforms and tagging a waveform to indicate whether it should be used in later processing, eliminating a response from further processing, automatically eliminating a response from further processing if a portion of the response exceeds a predetermined threshhold, smoothing a response by eliminating undesired high-frequency components, for adjusting the zero baseline of a response, eliminating selected portions of a response from further processing, and displaying in numerical form the value of a response at a point in time selected by the operator. These waveform quality control procedures enable the operator to improve the quality and accuracy of the topographic displays.

In another aspect, the invention features generating a topographic display of information on the electrical activity produced at a plurality of skull transducers; sampling and storing the information as a series of matrices; viewing the data as a waveform; adjusting or eliminating portions of the data, processing the matrices into processed matrices; interpolating to expand the matrices for viewing; and displaying the matrices as topographic maps in a grey tone scale. In preferred embodiments, the data matrices, processed matrices and expanded matrices can be tagged and stored for later recall and processing; and the data matrix elements can be calibrated to stored calibration signals by calculating a DC offset and gain component for each transducer. The ability to store display matrices for later use enables the operator to accumulate a series of significant matrices derived from diagnostic or research work. The calibration assures that the topographic displays will be accurate.

In another aspect, the invention features generating a topographic display of electrical activity of the brain produced from a plurality of electrical transducers on the skull; generating matrices of elements representing the electrical activity at different points; using a video monitor to display said matrices, each element of which is represented by a discrete point having a gray tone of color lying within a range of gray tones; and scaling the elements to the tones. In preferred embodiments, scaling can be performed so that all elements are linearly interpolated between the maximum gray tone and the minimum gray tone, or between the maximum gray tone and a "zero" gray tone, or to an operator supplied gray one, or so that certain display elements are excluded from the scaling, or that elements falling outside the available gray tone range are assigned to the closest gray tone; the gray tones can be generated in two colors, which can be complementary colors, representing values on either side of a zero tone, the zero tone being an absence of color; the scaling can be performed either on a matrix by matrix basis, or for all matrices taken together; the data which forms the input to the scaling operation can be previewed to by selected lab for exclusion from the scaling operation. The ability to scale the display data to a range of gray tones in a variety of ways improves the utility and visual effect of the display. The variety of scaling options is suitable for the variety of data which may be displayed. The ability to eliminate very large values from the scaling operation assures the most effective scaling for a given set of data.

In another aspect, the invention features normalizing display matrix elements to a selected value which can be assigned to a selected gray tone for purposes of scaling. In preferred embodiments, the normalization can be to a matrix element representing a particular vertex transducer on the skull, or to the root mean square value of the background activity at the transducer being normalized, or to the average root mean square value of the background activity at all skull locations; normalization can be done in connection with apparatus for topographically displaying a sequence of matrices representing averaged EP responses to repeatedly provided stimuli; normalization can be done in connection with apparatus for displaying spectral band matrices derived by Fourier transform analysis of the electrical activity, the normalization being of each element of each spectral band to the total spectral energy at the corresponding transducer on the average total spectral energy at all transducers. The ability to normalize display elements improves the operator's ability to compare different sets of data by normalizing them to the same value.

In preferred embodiments, the invention features interpolating to form additional matrix elements between the transducer points; the interpolation can be three-point interpolation, particularly three-point linear interpolation to the values of the three closest transducers; the number of transducers can be in the range of 10 to 200; and the number of picture elements is at least 5 times the number of transducers. The expansion of a matrix of a small number of points to a display matrix of a large number of points significantly improves the smoothness, readability and utility of the resulting topographic displays.

DESCRIPTION OF THE PREFERRED EMBODIMENT

We now turn to a description of the preferred embodiment.

System Organization and Software

FIG. 1 illustrates the components of a brain electrical activity mapping system. Twenty electrodes 5 (e.g., Grass gold cup) are attached to subject's skull 4 in a conventional international 10–20 format. Twenty leads 6 from electrodes 5 are connected through switch 7 to conventional 24-channel polygraph 10 (e.g., Grass 8-24D), which contains parallel variable gain differential amplifiers and strip chart recorders. Calibration signal source 8, an A.C. generator, is also connected through switch 7 to polygraph 10. Stimulus A 2 (e.g., Grass Model PS1 strobe light) and stimulus B 3 (e.g., click generator) present stimuli to the subject under the control of pseudorandom stimulus controller 9, which also provides pre-stimulus and stimulus trial marker signals (5 volt spikes) of opposite polarity to one of the input channels to 24-channel FM analog tape recorder 11 (e.g., Honeywell 5600E). In other embodiments, recorder 11 is eliminated and polygraph 10 is connected directly to filter 12 for real-time loading of data. The 21 active outputs of recorder 11 are connected to the inputs of 21 parallel variable band pass filters 12 (e.g., Butterworth filters; EEG Associates Mark 4×24) having variable gain controls. The 21 outputs of filters 12 are connected to 21 of the input terminals of two 16-channel, 12-bit analog-to-digital converters 15, 16 (Digital Equipment Corporation AA-11K), which comprise part of digital computer 13 (Digital Equipment Corporation PDP 11/60). Analog-to-digital converters 15, 16 are attached to data bus 14 (Digital Equipment Corporation Unibus). Also attached to data bus 14 are 4-channel, 12-bit digital-to-analog converter 17 (Digital Equipment Corporation AD-11K) whose three outputs control black and white television monitor 18 (Digital Equipment Corporation VR 17) for waveform displays; color display control 19 (Digital Equipment Corporation VSV 01) whose three outputs control 12" color television monitor 20 (CONRAC) for topographic displays; 8 serial line controller 24 (Digital Equipment Corporation DZ 11) two outputs of which control interactive keyboard and video character display terminal 22 (Digital Equipment Corporation VT 100) and printer 23 (Digital Equipment Corporation LA 120); 256K byte memory 24 containing operating system software 27 (Digital Equipment Corporation RSX 11/M), BEAM software 28 (Agrippa Data Systems), and analytic software 29 (TICAS; University of Arizona); floating point processor 25 (Digital Equipment Corporation FPP-11); central processing unit 26 (Digital Equipment Corporation PDP 11/60); and disk controller 27 controlling at least one disk drive 28.

Software Description

In general, the brain electrical activity mapping system creates color topographic displays reflecting brain electrical activity using, as input, continuous electrical waveforms recorded from a number of points on the skull. The color topographic displays consist of discrete matrices of a large number of display points (also called pixels), each of which has a color or intensity or other visible characteristic which indicates a certain value or values at the location of that point analogous to a point on the skull. In order to generate discrete topographic display matrices having many thousands of display points from continuous analog waveforms at a limited, e.g. 20, number of points on the skull, the brain electrical activity mapping system, as illustrated in FIG. 2, converts the data to digital form and generates discrete sample frames 40, each sample or frame initially comprising 20 recorded values 41 from 20 channels of information. The system treats related groups of samples 40 as segments 42. In the case of EP data, for example, a segment would consist of a series of frames or samples, each 4 milliseconds in length, the series together representing one transient response sequence from the beginning of a pre-stimulus period to the end of the post-stimulus transient response. In the case of steady-state EEG data, a segment would consist of 2 seconds of data divided into 256 samples. A spectral analysis of the EEG data then produces 256 samples, each of which reflects the energy level in a small, e.g. ½ Hz, energy band and a segment consists of the entire series of 256 spectral samples. For signal averaging purposes, the system considers a set of segments together, e.g., 500 segments each representing a transient response to a given stimulus. The 500 segments taken together are known as an ensemble 43. Frames of data can be raw data or data which has been processed or transformed by the system. In any case, as illustrated in FIG. 3, when a frame 40 is to be displayed it is expanded into a matrix 45 consisting of a large number of display points 46 which are determined by an interpolation process from the original frame data points 47. Each point of the matrix is then converted to a visual display point 47 which forms part of the final topographic display 48.

FIG. 4 illustrates the organization of the operations which comprise brain electrical activity mapping software 28 and TICAS analytic software 29. Raw and processed data is stored in disk files 51. Operations 52-65 and 67-69 use data stored in files 51 to perform data manipulation, data display and data storage functions. Operations 54 and 55 also process data from the outputs of converters 15, 16.

FIG. 5 illustrates the function of define protocols operation 53. Protocol files 73 are generated and edited by program 'SETPAR' 71 based on control information 70 provided by the operator through terminal 22, the results of the operation being displayed (block 72) on terminal 22 to the operator. Each protocol file 73 contains information which governs the manner in which other operations are performed on a particular type of data file (e.g., one protocol might apply to the processing of EP transient response data from strobe light stimuli). The protocol information may include the number and identity of input channels, the labeling of the output channels to correspond to specific points on the final display, the identity of the trial marker channel, the voltage level above which to search for the trial markers, the rate in samples per second of sampling of the data, the number of samples in a segment, the number of segments in an ensemble, the number of ensembles, the number of points in a baseline, the microvolt level of the calibration signal (e.g., 100 microvolts at 10 Hz), a multiplication factor, the number (up to 20) and size (width) of integration bands, the label of the protocol, the percent of taper of samples in a segment of data for fast fourier transform processing, the number of automatic smoothing passes, the high and low values for automatic rejection of data during accumulation, the stimulus interval and location in seconds, and channel labels related to electrode positions on the skull.

FIG. 6 illustrates the function of disk data sampling operation 54. Program 'DATCOL' 75 loads raw data from the output of converters 15, 16 into raw data file 79, which is divided into 19 buffers 80 which hold ensembles of data related to particular brain states or stimuli. The operator provides control information 76 designating the patient to whom the data relates and the name of the applicable protocol file 73. Other control information 76 governs the beginning, end, and pauses in data sampling, and the performance of a calibration of signal levels. Calibration data is initially stored in a buffer 80 of raw data file 79. When the operator requests (block 76) a calibration, and designates which buffer 80 contains the raw calibration data, program 'DATCOL' computes the root mean square value and the mean of at least 30,000 points in each channel of calibration data and divides the root mean square value by 0.707 to establish the assumed peak value of the calibration signal. The peak value, representing the level of the original calibration voltage, and the mean value, representing the D.C. offset of the calibration voltage value for each channel, are stored in calibration file 78.

The format of raw data as stored in raw data file 79 is illustrated in FIG. 7. Each buffer 80 contains header block 81, having protocol and other housekeeping information concerning the data stored in the buffer; calibration block 82 containing for each channel of data the calibration value in microvolts per bit and the number of microvolts by which the calibration signal was offset from zero both of which values were found in calibration file 78 at the time raw data was loaded; bad segment block 83 identifying segments of data which the operator will later decide to exclude from subsequent operations; an unused segment 84; and a series of data segments 85, which hold a series of data samples, each containing values for all 20 channels. The data segments 85 are interleaved with no gaps.

FIG. 8 illustrates the function of core averaging operation 55, usually usef for loading and signal averaging raw EP transient responses. Data from converters 15, 16 is read by program 'CORAVG' 86. User provided control information 88 designates the protocol, obtained from protcol file 73, under which the operation is performed, and determines start, end, and pauses of the operation. Program 'CORAVG' 86 samples data beginning at points labeled by the prerecorded trial markers and forms signal averaged EP transient responses from a series of transient responses resulting from repetition of a stimulus. The series of transient response data are accumulated and held in EP file 87, which is a reduced data file as described below. Calibration file 78 holds calibration information accumulated from the data channels in the manner previously described. Program 'CORAVG' 86 automatically rejects as "bad data" any segment which contains values outside of preset limits. Program 'CORAVG' also automatically adjusts the zero baseline with respect to each electrode's average EP transiet response, by subtracting the mean of the pre-stimulus period values for a channel from each point in that channel's transient response curve.

FIG. 9 illustrates a plot of an average EP transient response 90 of microvoltage against time as it could be displayed on monitor 18 following core averaging operation 55. The stimulus was presented at time 93, the transient response includes pre-stimulus period between time 92 and time 93, and the plot shows calculated zero baseline 91.

FIG. 10 illustrates the function of raw data quality control operation 56, which enables the operator interactively to review and eliminate bad segments of raw data before other operations are performed. By means of control information 94 the operator can select for review the contents of any buffer 80 in raw data file 79. The buffer data is displayed (block 105) segment by segment by program 'GLITCH' 95 on television monitor 18 to the operator as an analog waveform. The operator can label any segment of bad data, which causes the bad data segment to be identified on bad segment block 83. Control information 94 can also include the insertion of trial markers indicating a point on a waveform at which subsequent operations should begin, and display to the operator the microvolt value of individual points on a displayed curve.

FIG. 11 illustrates raw data topographic display operation 57, which provides topographic time sequenced displays (cartoons) of raw data frames. Program 'RAWMOV' 96 expands the 20 channels of each data frame into a matrix of 128×128 data points by three-point linear interpolation. The operator provides control information 102 designating the disk buffer 80 on raw data file 79 which contains the data to be displayed; the number of display matrices to be produced; the parameters for interframe interpolation; and the parameters and options (described below) for scaling the data points among the available grey color tones of the display. Program 'RAWMOV' 96 calculates each interpolated data point for the display matrix using three-point linear interpolation from the three closest original channels and scales the data to the available grey color tones of the display. The interpolation is performed using preset coefficients stored in interpolation file 97 by an operation described below.

The display matrices produced by program 'RAWMOV' 96 are stored in sequence in disk movie file 98. Program 'RAWDIS' will display (block 101) the frames stored in disk movie file 98 on monitor 20. Control information 100 permits the operator to designate the file to be displayed, the frame rate, and the starting, stopping and reversing of the display sequence. The displays include labels of information taken from the protocol block, e.g., patient identification.

FIG. 12 illustrates the functions of create interpolation file operation 52. Program 'POINTS' 110 creates points file 115 reflecting the X and Y coordinates of each point in the original electrode layout with respect to the 128×128 grid and associating with each point in the 128×128 display matrix the identity of the three original electrode points with respect to which it should be interpolated. Control information 120 provided by the operator includes the X and Y coordinates of each channel and the identity of the three interpolation points for each display point. Program 'OUTLINE' 111 identifies and stores in outline file 116 the X and Y coordinates of the points which outline the plan view of the skull to be included in the display, based on control information 121. Program 'MAKCOF' 112 generates and stores in coefficient file 117 the coefficients needed to perform the three-point linear interpolation for each matrix display point within the skull outline, using points file 115 and outline file 116 as input. Program 'MAKOVR' 113 stores in overlay file 118 the operator provided (block 123) coordinates of the overlay of the skull, nose and ears outline for the display. Program 'SETOVR' 114 generates interpolation file 119 from overlay file 118 and coefficient file 117. Interpolation file 119 then contains the information required to compute interpolated matrix data points and the skull overlay for display.

FIG. 13 illustrates the function of the raw data reduction operation 58. Three alternative programs can operate on data in buffers 80 to produce reduced data files 125. Program 'DSKFFT' 126 accepts segments of EEG data from raw data file 79, performs a fast fourier transform analysis which produces a new segment of data reflecting the spectral energy in each of a sequence of frequency bands. Program 'DSKFFT' 126 also generates, for each group of segments, an ensemble consisting of the sums (used in a later step to form the average values) and sums squared (used in a later step to form the standard deviations) for each channel across all segments in the group, values reflecting each of the sums as a percentage of the total spectral energy in the segment, and values reflecting the coefficient of variation (the standard deviation divided by the mean) for each channel across an ensemble. FIG. 15 illustrates the format of the resulting ensemble of FFT data stored in reduced data file 125. The sums data 130 is filed in sequence by channel for the first frequency band 131, e.g., 0.5 Hz. Similar sums data follows for the other frequency bands. After all sums data is stored, the sums squared data 132, the normalized power spectral density sums, and the coefficient of variation data are stored in similar fashion. In addition to storing the sums and sums squared data for all segments in the ensemble, program 'DSKFFT' can store spectral information for each segment analyzed. As illustrated in FIG. 16, the data is stored as sine and cosine coefficients for each channel for each frequency band, and as normalized sine and cosine coefficients as a percentage of total spectral energy. As illustrated in FIG. 18, the FFt data file 191 stored on reduced data file 125 also includes a header block 192 housekeeping information.

In FIG. 13, program 'DSKAVG' 127 performs a function similar to core averaging operation 55 in signal averaging EP transient response waveforms, but uses as input raw data stored in raw data file 79 and permits the operator to review each waveform and select those to be used in the averaging process, rejecting others. Program 'MANAVG' 128 permits a similar operator-assisted signal averaging process when the raw data does no contain preset stimulus trial markers, requiring the operator to indicate the point at which averaging is to begin for each waveform. FIG. 14 illustrates the format of signal averaged data produced by programs 'CORAVG' 86, 'DSKAVG' 127 and 'MANAVG' 128. The sums of each channel for all trials for the first time frame 133, e.g., 0–4 milliseconds, are loaded in order, followed by similar information with respect to all subsequent time frames for a given segment. As illustrated in FIG. 17, such EP files 190 are preceded by header block 193.

FIG. 19 illustrates the function of reduced data quality control operation 59, which permits the operator interactively to review and modify data in reduced data file 125. By providing control information 204, the operator can select the file to be reviewed and indicate whether it contains FFT spectral information or EP time-sequenced information. For FFT information, program 'FFTLUK' 201 displays (block 202)selected channels of spectral data as frequency-voltage curves on monitor 18 and permits the operator to low-pass filter the waveforms and display the value of particular data points. For EP data, program 'EPLUK' 203 displays (block 202) selected channels as time-voltage curves and permits the operator to reset the zero baseline, to filter high frequency noise from a channel, and to display the value of any point on a curve. FIG. 20 illustrates the function of manual baseline relocation. Because pre-stimulus period response 180 was not level, automatic baseline 176 set by program 'CORAVG' 86 inaccurately reflects the true zero level for transient response curve 175. The operator can relocate the baseline to a new level 177 by moving cursor 179 to the desired level, causing that voltage value to be subtracted from each point of data along curves 180 and 175.

FIG. 21 illustrates the functions of reduced data topographic display operation 60. For single frame display of FFt data, program 'FFTTVM' 206 reads data from reduced data file 125 as selected by operator control information 214. The data is scaled in accordance with instructions included in control information 214. The selected frame is provided to program 'TVM16' 213 which interpolates a matrix of 128×128 points using the coefficients and other information contained in interpolation file 97, and provides the resulting matrix to color display 212. For single frame EP display, program 'EPTVM' 205 performs an analogous process to that of program 'FFTTVM' 206. Programs 'EPTVM' 205 and 'FFTTVM' 206 also perform compilations of sequences of frames into one display matrix, in accordance with predefined groupings set forth in protocol blocks.

A sequence of FFT matrices or EP matrices can be displayed in rapid time sequence as a cartoon by the use of program 'FFTMOV' 208 and program 'EPMOV' 207, respectively, each of which processes sequences of selected matrices of data from reduced data file 125, using scaling control information 215; interpolates full 128>128 matrices for each frame; interpolates a selected number of additional matrices between the original frames; and stores the resulting matrices in movie file 211. Based on control information 216 specifying data to be displayed, the frame rate of display, start, stop, backward, forward and pause, program 'FFTDIS' 210 and program 'EPDIS' 209 provide cartooned matrices for viewing on color display 212.

FIG. 22 illustrates group file production operation 61. Program 'GRPBLD' 221 creates and updates a composite group file 223 working from selected individual reduced data files 125. Control information 222 provided by the operator indicates the identity of individual reduced data files to be included. The group files 223 consist of the sums and the sums squared for all homologous points in the reduced data files 125 of all individuals in the group. Normalized sums and coefficients of variation may also be produced and stored. Hard copy 224 listing the individuals in each group and the values of group file data are available based on control information 222.

FIG. 23 illustrates the function of group topographic data display operation 62 which is analogous to the operation of the single frame display of reduced data file information, illustrated in FIG. 21, except that the data displayed is from group file 223 instead of reduced data file 125.

FIG. 24 illustrates the function of individual versus group comparison operation 63. Programs 'EPTVM' 205 and 'FFTTVM' 206 are performed respectively on EP and FTT data. In each case, the program generates a frame of points, each of which is the number of standard deviations (z-statistics) by which an individual's point, taken from individual file 226 differs from the average of the group's corresponding points taken from group file 223. The resulting frame is displayed (block 216) by program 'TVM16' 213, which interpolates additional data points to form a 128×128 matrix in the manner previously described.

FIG. 25 illustrates the function of group difference detection and feature selection operation 64, which computes frames of t-statistics reflecting the level of statistical difference between two groups based on the means and standard deviations of homologous data points for the two groups. Program 'GRPCMP' 230 computes t-statistics and degrees of freedom from the sums and sums squared data contained in two different group files 223 designated in control information 231 provided by the operator. The resulting frames are stored in group comparison file 232. Based on file and frame designations set forth by the operator in control information 235, program 'GRPDIS' 234 transmits a selected t-statistic frame for display by program 'TVM16' 213 as previously deascribed. Program 'TVM16' 213 also returns a fully expanded 128×128 matrix back to program 'GRPDIS' 234. Through control information 235, the operator may store such a t-statistic matrix in saved frame file 233. FIG. 26 illustrates the format of saved frame file 233. Header block 240 contains the number of saved frames, and for each frame identifies the time frame length or frequency band and the protocol under which the data was collected. Frames 241 contain 128×128 matrices of floating point t-statistics generated by program 'GRPDIS' 234.

FIG. 27 illustrates the functions of the brain electrical activity mapping to TICAS file transfer operation 65, which converts features of brain electrical activity mapping data to a form usable with TICAS software 29. Program 'FEADEF' 245 generates feature list file 247 from feature definitions and names of saved frame files 234 provided by the operator in control information 246. Program 'FEAGET' 248 then generates TICAS formal file 249 from reduced data files 125, saved frame file 233, and feature list file 247, identified by the operator in control information 250. The feature definitions which may be selected and stored in TICAS format file 249 for subsequent TICAS analysis include nearly all combinations of data found in all individual files, all combinations of integrated bands of frames (e.g., alpha bands) in individual files grouped according to preset protocol specifications, or combinations of individual frame files weighted by the values in a saved t-statistic frame.

FIG. 28 illustrates the functions of TICAS feature selection and evaluation operation 67. In control information 266, 264 the operator designates two groups 262, 263 from TICAS format file 249 whose features are to be analyzed, the type of data to be analyzed, the number of input features to be analyzed, and the number of output features to be produced. Program 'UTEST' 261 peforms a standard two-sample Wilcox-Mann-Whitney U-test and provides a list of U-test scores in rank order which are printed on printer 23 and stored. Program 'FMTST' 260 performs a final merit value (FMV) test and provides and stores a list of values for features in order of final merit values. Program 'FMTST' 260 first determines intermediate merit values as a combination of the standard receiver operating characteristic (ROC) curve or d' value and the results of an ambiguity function analysis. The final merit values for each feature are then determined by correlation of the intermediate merit value with all features ranked higher in intermediate value. Program 'MERGE' 267 selects from Group

A features 268 and group B features 269, based on the FMV values and U values, those features which are most useful, which are then stored in disk files 270 and 271.

FIG. 29 illustrates the functions of TICAS generate discision rules operation 68. Program 'SLPRT' 275 uses an operator controlled (block 278) subset of selected Group A features 276 and selected Group B features 277 to generate disk stored interim rules 279, by a method controlled (block 278) by the operator. The computation method may be a non-parametric d-selection technique, a parametric classification technique, or a combination of the two. Program 'CLSFY' 284 uses operator selected (block 285) interim rules 279 to classify operator selected subjects having operator selected features, from selected group features files 280 or refined group features files 281, 282, printing the results on printer 23, thereby permitting the operator to evaluate the efficacy of each selected interim rule 279. Progran 'DSC' 286 combines operator chosen (289) features from selected Group A features 287 and selected Group B features 288 into new features on the basis of the weighting functions of a standard linear discriminate analysis, subject to the operator's choice (group 289) of discriminant function parameters. Discriminant function weights for the best features are then loaded into a disk file 290. Program 'LINCOM B' 293 uses the original selected Group A features 291 and selected Group B features 292 and the discriminate function weights 29 to create refined Group A features 294 and refined Group B features 295, which are linear or other operator selected (block 296) combinations of the original features. Refined Group A features 294 and refined Group B features 295 can replace the original selected features 276 and 277 as input to program 'SLPRT' 275 to permit an iterative process of decision rule generation.

FIG. 30 illustrates test decision rules operation 69. Program 'CLSFY' 284 uses final sets of decision rules, e.g., rules A 304 and rules B 305, to classify individuals in original Group A 300, original Group B 301 and new unknown groups, e.g., Group C 302 and Group D 303, to determine the efficacy of the final decision rules, the results being provided on printer 23.

Operation

Data Gathering

Accumulation of raw EEG and EP data is accomplished by first attaching 20 electrodes 5 to the scalp of an individual subject in a conventional international 10-20 format. In other embodiments, information from between 10 and 200 electrodes can be gathered and analyzed. Before recording, and if desired during recording, the operator observes the signal levels on the 20 channels of chart recording of polygraph 10 and adjusts the gain on weak signals to produce usable waveforms. A calibration signal of 100 microvolts (10 Hz) from source 8 is recorded on all twenty channels on tape recorder 11 at the beginning of each session and whenever any of the gain levels on polygraph 10 is adjusted.

Data gathering typically begins with a careful administration of a sequence of tests, each of which is intended to establish a particular steady-state electrical condition in the subject's brain. The sequence of tests usually includes instructions to relax and remain still with eyes open, to relax and remain still with eyes closed, to become drowsy, to breathe deeply for hyperventilation, to listen to music and to listen to speech. Other tests rewquire the subject to (1) listen carefully to a story and answer simple questions about its content when completed, (2) remember a set of six abstract figures (often resembling an unknown language alphabet) in black ink on index cards presented by the examiner, (Kimura Figures-Instruction) (3) select the six previously presented figures from a set of 38 figures, verbally indicating yes or no (Kimura Figures-Test), (4) associate each of four abstract figures on index cards with a particular artificial name spoken by the examiner (Paired Associates-Instruction), (5) name each of the four abstract figures when tested by the examiner (Paired Associates-Test), (6) read silently three previously unread paragraphs (e.g., example text from the Gray Oral Reading Test) so as to answer questions subsequently (Reading Test-Instruction), (7) identify whether 34 typed sentences presented by the examiner were previously included in the three paragraphs (Reading Test-Test), and (8) read text upside down. The tests are designed to permit recording of brain electrical signals during simple resting brain activity and during different levels of activation of the left hemisphere, the right hemisphere and both hemispheres of the brain together. This permits the demonstration of pathologies present at rest and those present upon brain activation. The development of specific tests and the choice of tests is determined by the user based in part on the subject being tested and the information eing sought as described in greater detail below. Between twenty seconds and three minutes of steady state brain electrical activity is recorded on all 20 channels during each of the tests. Appropriate records of the tape location of each test are kept. These tests have been used with the brain electrical activity mapping system to demonstrate group differences between normal subjects and those with dyslexia or specific reading disability at the 10-12 year age level and at the six-year age level; to differentiatedemented patients from normals and aged patients from younger patients in clinical settings; to identify patients with an organic basis for sociopathic behavior and other forms of mental illness; to demonstrate epilepsy when the resting background EEG failed to show any abnormalities; to demonstrate abnormalities in EEg and EP data for schizophrenic subjects; and to determine when a brain tumor, previously treated, is about to recur.

With young infants, the brain states tested include sleep, alert and attending to visual and auditory stimuli, alert but not attending to visual and auditory information, and drowsiness. Using these states, it is possible to discriminate among children with poor behavioral scores on a psychological test and those with high psychological scores.

A series of sensory evoked potential (EP) transient responses are then recorded from all electrodes while the subject is repeatedly exposed to a selected stimulus, e.g., a strobe light or a click generator or to a predetermined sequence of two alternate stimuli. Because the EP transient response is weak compared to the background steady-state brain electrical activity, the stimulus must be presented many times (e.g., 500) to the subject for later signal averaging. The total response period of interest is typically 1024 milliseconds, comprising 512 milliseconds before stimulus and 512 milliseconds after stimulus. The process is repeated for different stimuli.

Stimuli presented to the subject can range from simple flash, simple click, simple pattern reversal and simple somatosensory stimulation to those requiring complex decisions. Requiring a subject to discriminate between subtly different auditory stimuli (e.g., the words "tight" and "tyke") is useful in diagnosing dyslexia. This procedure is known as the Tight-Tyke evoked potential phenomic discrimination test. Picking an infrequently different stimulus from among other more frequent stimuli is useful evaluating subjects who have functional brain disorder.

Auditory stimuli generate a set of fast and a set of slow transient responses. The fast responses eminate from the brainstem and have a typical duration of 20 milliseconds. Brainstem responses are normally sampled for a total response period of 40 milliseconds comprising 20 milliseconds before stimulus and 20 milliseconds after stimulus. Filters 12 are adjusted to exclude frequencies below 300 Hz and to include frequencies up to 8000 Hz.

When EP transient responses from such stimuli are averaged to eliminate noise, two types of interference can occur. The first type, known as contingent negative variation (CNV), relates to the connection made by the brain between consecutive equally spaced stimuli when the subject is told to count the stimuli. The D.C. component of the resulting transient response shows a gentle dip and a sharp rise immediately before each stimulus, attributable to the subject's anticipation of the next stimulus. The sharp rise contaminates the evoked potential transient response and makes it difficult to establish a zero baseline. By including as part of the interval between stimuli a first pseudorandom time element which varies from 0 to a period longer than the post-stimulus response and is also a multiple of the wavelength of the interfering frequency described below, the CNV effect is greatly reduced.

The second type of interference results from the existence of background noise at certain characteristic frequencies, e.g., 10 Hz, which reflect prominent bands of steady-state brain wave activity. The major interfering frequency of a given subject may be determined by a spectral analysis of his background EEG signal. The interference problem is especially significant in adults with prominent alpha waves and children with prominent slow brain wave activity. By including in the time interval between stimuli a second pseudorandom time element whose period varies from zero to the wavelength of the major interfering frequency, the background noise can be substantially reduced in the averaging process.

The inclusion of a prestimulus period of recoding for each transient response permits an accurate baseline determination at a later stage of signal processing in order to establish a true zero level for the post-stimulus response and permits a determination of the quality of the signal averaging process.

Pseudorandom stimulus controller 9 measures the interval between stimuli as a combination of the post-stimulus response period, the first pseudorandom period described above, the second pseudorandom period described above, and the pre-stimulus response period.

As illustrated in FIG. 31, pseudorandom stimulus controller 9 comprises a four-stage timer, each stage of which in turn measures one of the four periods included in the interval between stimuli. The first stage comparator 406 measures the pre-stimulus period p_1/f_{c1} where P_1 is a number preset by the operator in register 408 and f_{c1} is the frequency set on variable frequency clock 404. When the first stage timing is completed, the second stage times the post-stimulus period as P_2/f_{c2} where P_2 is a number preset in register 414 and f_{c2} is the preset frequency on clock 410. At the end of the first stage timing period, a stimulus trial marker (5 volt spike) is recorded on the trial marker channel of tape recorder 11 and stimulus 409 is triggered. The selected post-stimulus period is long enough to permit a full decay of the transient response being observed. At the end of the second stage timing period, the third stage measures the first pseudorandom time period P_3/f_{c3}, where P_3 is the next pseudorandom number in programmable read only memory (PROM) 419 and f_{c3} is the preset frequency of variable clock 415. PROM 419 has been preloaded with a pseudorandom sequence of numbers. At the end of the third stage timing, the fourth stage measures a second pseudorandom period in an analogous manner based on a pseudorandom sequence in PROM 424 and a preset frequency on clock 420. When the fourth stage timing period is over, a pre-stimulus trial marker (5 volt spike) is recorded on the trial marker channel of recorder 11. A new timing cycle is then completed and the process is reiterated until the total number of transient responses recorded equals a preset number in register 426 or the process is stopped by the operator. The entire process is begun by pushing button 401, which causes the recording of a pre-stimulus trial marker. Temporary delay button 431 can be used to temporarily delay the continued operation of the timer at the operator's discretion, as for example when the subject is distracted in a manner which would render the transient response useless. A low order bit in PROM 424 or PROM 419 can be set to 0 or 1 by the operator for each number loaded into PROM 24 or PROM 19 so that two different stimuli (e.g., auditory and visual) can be triggered in a preselected order or pattern, with one stimuli being presented more frequently than the other.

The result of the recording session is an analog tape of raw EEG and EP voltage data and calibration voltages on 20 channels with trial markers on a twenty-first channel. The next step is to load the data into computer 13.

As previously described, brain electrical activity mapping software 28 performs data collection, data manipulation, and data display functions in accordance with central information provided by the operator. The various operations can be performed in any sequence and the operator can perform a series of functions iteratively. The operator provides control information through the keyboard of terminal 22 and receives information concerning the various operations on printer 23, waveform monitor 18 and topographic color monitor 20. The flexibility of operation heightens the system's utility as a diagnostic and analytical tool.

Data Loading

Under operator control,EEg data for each brain state and related calibration signals are loaded directly onto disk storage from recorder 11 after passing through filters 12 set to pass frequency components between 0.5 and 50 Hz or between 0.5 and 1000 Hz and epileptic spike data. Gain controls on the filters are adjusted to fully utilize the signal capacity of converters 15, 16. EEG data can be sampled at rates as high as 20,000 samples per second.

Under operator control, EP data is passed through filters 12 set to eliminate frequencies above a selected frequency of between 40 and 100 Hz, or below 300 Hz for brainstem data, and is signal averaged in core memory using core averaging operation 55, which automatically rejects bad data and sets the zero baseline.

Typically EP data is sampled every 4 milliseconds, or every microseconds for brainstem analysis, and 256 sampled are taken, 128 pre-stimulus and 128 post-stimulus. If the operator determines that the EP transient response data is very noisy, he may alternatively record the data as raw data and use raw data reduction operation 58 to average only selected transient response trials. In cases where the transient response data may not contain the necessary stimulus trial markers, such as in recordings of rapid eye movement (REM) sleep, the data can similarly be recorded as raw data and trial markers can be added manually by the operator, using raw data operation 58, before signal averaging is done.

Raw Data Quality Control and Display

To assure the maximum accuracy and utility of raw data, the operator can, using raw data quality control operations 56, display recorded waveforms, accept or reject each waveform for later processing, have mathematical smoothing operations performed, reset baselines or eliminate certain points of data.

The operator views the EP transient responses for the 20 channels for the purpose of evaluating the utility of each curve and specifying modifications which will improve their utility when displayed. The operator may direct a further adjustment of the baseline, which has already been set automatically, by having a constant number added to or subtracted from the value in each frame, or can determine to have the automatic baseline determination redone using a smaller number of the later pre-stimulus frames as the baseline. This procedure is particularly useful when the early pre-stimulus frames are found to contain the tail end of the transient response of the prior stimulus. By reviewing the relative levels of V_{RMS} (pre-stimulus) and V_{RMS} (post-stimulus) for a given channel, the operator can determine whether the background noise level is unacceptably large with respect to the transient response, necessitating another recording session with the subject. The operator may also filter any high frequency noise in the post-stimulus period by three-point interpolation.

As part of the raw data quality control process, if a channel contains spurious values (e.g., voltage spikes) in particular frames, the operator can eliminate those values and substitute values interpolated from the next prior and next later frames. If the voltage levels on one channel are substantially higher than for the other channels, the operator can flag that channel to indicate that the channel should be excluded from the subsequent display scaling procedure (described below). Based on the operator's instructions, the automatic baseline determination may be redone and the results are viewed again until the operator is satisfied that the set of transient responses contain satisfactorily low noise levels and are properly zeroed.

Raw data topographic display operation 57 enables the operator to display a cartoon series of topographic maps of raw data, which has been expanded by interpolation into a matrix of 128 × 128 points. The cartoon can be started or stopped and run forward or reversed at will. When raw EEG data is to be cartooned, the operator can sample the data at a high rate, e.g., 400 frames per second, and then display the information at slower speed or in a series of matrices, each of which is an average of a sequence of frames. The averaging can be done on a running basis, so that the first N frames are averaged and displayed, then the N frames beginning with the second frame are averaged and displayed, and so on.

EEG Data Reduction

Raw EEG data is converted to spectral data using the fast Fourier transform process of raw data operation 58, as previously described. The segments of raw EEG curves whose spectral data is averaged are generally about 2 seconds in length each, which is shorter than the average period between spurious artifact signals. Typically from 15 to 90 segments are spectrally analyzed and the spectra averaged. The spectra usually consist of 128 frequency bands of ½ Hz in width covering the spectrum from 0 to 64 Hz. The ends of each segment can be tapered in accordance with the operator's discretion in connection with the Fourier transform process.

Reduced Data Quality Control and Topographic Display

Working with reduced EP and EEG data, that is sequences of time frames of transient response data and groups of spectral band data, the operator can use reduced data quality control operation 59 to view the waveforms, discard bad data reflecting movement artifact, eye blink, or muscle activity and eliminate high frequency noise. The reduced data can then be topographically displayed on a frame by frame or cartooned basis using the reduced data topographic display operation 60. In either case, the operator can form frames which represent combinations of underlying frames. For example, groups of ½ Hz bandwidth frames can be combined into larger bandwidth frames corresponding with typical spectra of clinical interest, e.g., alpha, beta, delta and theta. Bands of any desired width can be formed. In addition to displaying raw spectral energy information from EEG data, it is possible to display normalized spectral energy in which the points on each display are normalized to the overall spectral energy of each electrode or to the average overall spectral energy at all electrodes. In the case of EP data, it is similarly possible to display each point as a normalized value to the value at one specific electrode, e.g., the vertex electrode designated "C_z", or to a standardized value, or to a selected value, or to the V_{RMS} of the background activity at each electrode, or to the V_{RMS} of all electrodes. Similarly, the 128 frames of an EP transient response can be grouped into frames of greater time duration for display.

Group Data Analysis

By accumulating a number of stored data frames, it is possible for the operator to assemble and display group data files using group file production operation 61 and group topographic data display operation 62.

Significance Probability Mapping (SPM)

Using stored data for various groups and individuals, the operator can perform and display topographically t-statistic comparisons between groups of frames and z-statistic comparisions between an individual frame and a group of frames. Any other statistical group comparison can also be used to form a display matrix to illustrate group differences. This type of analysis, significance probability mapping (SPM), enables the operator to identify significant brain activity features related to various neurophysiological illnesses and conditions.

Grid Sector Analysis

Frames produced by the SPM procedure may be further analyzed by a Grid Sector Analysis (GSA). While the frames produced by the SPM procedure reflect regional abnormalities, the GSA procedure produces numerical measures of the degree of global or focal deviations from normal, which can assist in automatic determination of the existence of regional abnormalities in unknown subjects.

The first step of the GSA process conceptually requires the division of a frame into a number of different grids, each divided into sectors of a uniform size. Within each grid sector, the mean of all values of the data points lying within the sector is determined as the value of that sector. The process is repeated for grids of different fineness. Preferably three grids, of 4000 sectors, 64 sectors, and 16 sectors respectively, are used. Histograms of sector values are then prepared for each grid reflecting sector t-statistic or z-statistic values on the horizontal axis and numbers of sectors having that value on the vertical axis for each grid. Various analyses of the histrograms, which differ for focal and global abnormalities, will indicate whether an abnormality is focal, i.e., localized in one area, or global, i.e., diffused over a large part of the brain. One such analysis would simply be the observation that the peak number of sectors for the coarser grids will be at lower z or t values in the case of a global abnormality than in the case of a focal abnormality.

In the case of focal abnormalities, there is a marked difference in the histograms for the three grids, while in the case of global abnormalities, there is little or no difference for the three grids. A variety of features can be developed from the histograms to serve as possible diagnostic rules. The maximum z-value for each grid, the maximum amount of asymmetry between homologous grid regions, the mean asymmetry between homologous grid regions, and the difference between the absolute values of the sum of all left hemisphere and all right hemisphere values. Also, one can calculate the number of regions above certain criterion levels for each histogram.

A group of spectral maps or a series of EP responses can be analyzed as an ensemble by forming at each matrix point the mean of the values of each map in the ensemble. The grid region on each individual map showing the largest value is given a score of 4, the next largest a score of 2, the third largest a score of 1, and the rest a score of 0. The scores are then summed by region across all maps in the ensemble, and the regions having the three largest scores and their sum are stored as indications of focal features. The same process is repeated for the three regions having the greatest asymmetries in each image between corresponding grid sectors. The resulting information can serve as features which can be processed using TICAS to develop diagnostic rules to classify unknown subjects between a group of normals and a group having a particular dysfunction. The numerical descriptors generated by GSA, when used for statistical analysis are approximately as successful in the identification of patients with brain tumors as visual inspection of EEG data by expert clinicians.

Coefficient of Variation Analysis

Given an ensemble of segments of data, the operator can determine the mean and the standard deviation of each point across the segments. By displaying the standard deviations as percentages of mean at each point, the coefficient of variation (C/V) across the skull can be observed topographically. The normal expect range of C/V values is 40–60% and deviations from that range are immediately evident from the displays. The C/V display is useful in demonstrating head regions where there are wide variations in activity, e.g., epileptogenic regions.

Difference Maps

A display matrix can be formed to represent at each point, the difference in value of corresponding points on two underlying frames. This permits, for example, displays which suggest the regions of the brain activated by patterned light, by comparing the frames corresponding to plain light stimulation and to patterned light stimulation.

Automatic Diagnostic Rules

Working from significant brain activity features and using TICAS-related operations 65, 67, 68 and 69, the operator can develop and test diagnostic rules for accurately classifying unknown subjects between normal and abnormal groups.

Scaling

Several of the available BEAM system operations produce color topographic displays. Video monitor displays typically involve assigning to each point on the display a grey tone of color which represents the value of the point. Sixteen tones of color represent 16 different graduated values. For example, red can be used for positive values and blue can be used for negative values with the grey tone of blue or red indicating the level of positive or negative value. An absence of color represents zero. In order to maximize the visual effectiveness of the display, it is desirable to scale the values of the data points to the available color tone levels in such a way that the useful variations in value are spread among the maximum range of color tones. The scaling can be done according to a variety of options. The data points can be scaled so that the maximum absolute value of the data points over a set of matrices will be equivalent to the maximum positive and negative color tones and all other points will be scaled linearly to the intermediate color tones. Scaling can be done from zero to the maximum absolute value. The same scaling technique can be accomplished with one or more channels excluded by the operator from the scaling process so that unusually high value data points will not skew the scaling process. Scaling can be done on a matrix by matrix basis rather than across a group of matrices. Scaling can be done to a maximum value chosen by the operator. In the scaling process, any data value which is larger than the brightest available grey color will be truncated and displayed as that brightest color.

Three-Point Linear Interpolation

Since the data frames to be presented for display originally contain a relatively small number of points, e.g., 20 points, and the display is preferably of a continuous matrix of 128 × 128 points, expansion of the data by some form of interpolation is required. The expansion is accomplished by three-point linear interpolation, in which each display point is determined as a sum of the values of the three nearest data points on the original data frame, each multiplied by a predetermined coefficient which reflects the precise location of the display point. As an alternative to the software previously described, the calculation of the display point can be done on hardware having an extremely short processing time, making possible "real-time" displays, that is, each display matrix is calculated in a time shorter than the display time for each display matrix. A detailed description of the three-point interpolation technique is contained in U.S. patent application Ser. No. 221,830 (hereby incorporated by reference).

Display Features; Multidimensional Display

As illustrated in FIG. 32, the each topographic display comprises an outline of the skull with an indication of its orientation with respect to the ears and nose. All display points outside the outline are suppressed. Within the skull outline are displayed the grid of data points, each of which reflects a value or values for that point on the skull. The number of dimensions of information which may be represented by a given point varies with the display method. Frequently only one dimension of information is presented at any point in the form of a grey-tone of color on a predetermined grey-tone scale. Alternatively additional dimensions may be reflected at a point as a unique combination of three colors. Three dimensions can be represented by the quantity of each of the original colors which is mixed into the combination and a fourth dimension could be the lightness or darkness of the three. In this manner, for example, spectral EEG data for four frequency bands of brain activity could be displayed simultaneously. A detailed description of this four-dimensional display is contained in U.S. patent application Ser. No. 221,830.

Whenever displays are cartooned, the operator may select the frame rate of display from stationary to ten frames per second minimum. The cartoon can also be displayed legarithmically with time, so that the later matrices are displayed in faster sequence then the earlier ones, which visually compensates for the fact that more EP response information is available just after the stimulus than toward the end of the response period.

Examples of System Use

The brain electrical activity mapping system offers a powerful brain diagnostic and research tool by permitting immediate video display of information about steady-state brain waves, EP transient responses, spectral analyses of EEG signals, and statistical information based on these types of data, and the ability to develop diagnostic rules from selected features of data. The following examples illustrate the versatility and utility of the system.

Suspected Epilepsy

Although the "spike and wave" as seen on routine EEG graphs is virtually diagnostic of epilepsy, over 10% of all true epileptics fail to demonstrate this abnormality. Use of special electrodes, sleep studies, and activating drugs often fails to produce spikes in true epileptics. This means that although an epileptic may have brain cortex that is capable of demonstrating sufficient irritability at times to produce a seizure, that at other times it fails to be sufficiently irritative to produce a spike on the EEG and thus eludes diagnosis. Topographic display is of great assistance in such situations. Such suspected epileptic patients should have eyes open (EO) and eyes closed (EC) topographic studies performed. Irritative cortex presents itself as focal increases of activity over all frequency bands, especially the high frequency beta bands. The visual evoked EP response (VER) topographic study should also be performed. Irritative cortex leads to focal increases of both positive and negative waves. If the epilepsy is associated with an atrophic lesion, a region of reduced EEG and EP activity may be found in close association with the focal irritability.

When spikes are found, displays of their topographic extent are extremely useful in determining their point of origin. In this case, raw EEG data is displayed in cartoon form thus delineating the epileptic dipole.

Suspected Supratentorial Brain Lesion

Patients are often referred for EEG tests in order to rule in or out a lesion of one or both cerebral hemispheres. This includes tumor, stroke, abscess, atrophy, arterio-venous malformation, congenital malformation, hemorrhage, regional encephalitis. These subjects should be subjected to topographic studies in the eyes open and eyes closed brain states, and for the VER and bilateral somotosensory evoked response (BSER) EP situations. In general these lesions may be recognized by the pattern of hypo- or hyperactive cortex that become visible on the brain electrical activity mapping images. For example, tumors show decrease in activity early, excessive activities later, and reduced activity at the vertex. Brain electrical activity mapping greatly adds to the information obtained by radiographic scanning as it is sensitive to the functional disturbances produced by these lesions which usually extend beyond the anatomical limits of the lesion.

To pinpoint abnormalities the technique of significance probability mapping (SPM) should be used. Furthermore, quantification of a lesion by grid sector analysis (GSA) is often useful.

Brain electrical activity mapping is most useful when tests must be applied to a large population for screening purposes or repeatedly to a single person. Such uses would include screening for tumor and stroke, determining whether a lesion is increasing or decreasing, and assessing the effects of treatment on a lesion. Brain electrical activity mapping is completely non-invasive, and not dangerous as radiographic techniques would be in such circumstances. There is also evidence that many lesions produce electrical (functional) disturbances before they can be detected by radiographic means.

Suspected Learning Disabilities

Brain electrical activity mapping studies are most useful in the elucidation of regional abnormalities of brain activity found in dyslexia, hyperactivity, dyscalculia, and combinations of the above. For example, dyslexia reveals abnormalities not just in the classic left temporal lobe speech areas but in the medial frontal lobe bilaterally. To demonstrate these abnormalities, one needs to perform the full test battery which includes: right hemispheric activating tests (the Kimura Figures task and listening to music as described elsewhere); left hemispheric activating (listening to speech and reading Grey Oral passages as described elsewhere); and bi-hemispheral tests (Paired Associates test and the Tight-Tyke evoked potential phenomic discrimination test as described elsewhere).

Automated classification tests to discriminate among these clinical entities can be developed.

Emotional Dysfunction

Many forms of emotional disorder can be caused by the lesions mentioned above. Brain electrical activity mapping can be more useful in the recognition of covert pathology in this patient population than radiographic techniques. In addition, certain forms of psychopathology have recognizable brain electrical activity mapping signatures. For example sociopathic behavior is associated with lack of synchrony between the frontal lobes; e.g., the VER may show different electrical polarity between the right and left frontal lobes. Schizophrenia shows markedly increased EEG slow activity overlying the frontal regions. In this group of subjects, the eyes open and eyes closed EEG and VER studies are most useful.

Infant Competence

Discrimination between babies at risk for future learning and emotional problems is a frequent clinical request. Brain electrical activity mapping has proven useful in accomplishing such discrimination. In addition to studying the EEG and VER in stages 1 and 2 sleep, the EEG should be studied while the babies are brought into the alert state and maintained there as discussed elsewhere. Less competent babies, for example, show paradoxical increases in frontal delta slowing as they are alerted.

Suspected Dementia

Senile and pre-senile dementia represent a major problem for gerontologists and neurologists. Radiograpic evidence of brain abnormality may not be found until the clinical symptom complex is well established. On the other hand, brain electrical activity mapping studies demonstrate early abnormalities in a non-invasive manner. The best battery of tests is similar to those described above for suspected learning disabilities, but generally the tight-tyke EP is replaced by another EP where the subject must discriminate between frequently and infrequently heard tone pips of differing frequency. A difference EP between the response to the two different tone pips is produced. The topographic display of the difference EP shows a marked reduction in dementia and may be used to follow the course of dementia and the response of dementia to pharmacotherapies.

Headache

Headache may be caused by many factors. Brain electrical activity mapping is very useful to screen out serious lesions of the types described as supratentorial lesions above. The specific syndrome of migraine headache has a frequently seen pattern on brain electrical activity mapping of excessive 8-11 Hz occipital oscillations and excessive occipital activity. It is best to use the EO and EC EEG and VER for headache. Occasionally the BSEP is useful.

Comparison of Individual to Group

As described above, the brain electrical activity mapping system is generally able to compare an individual statistically to a group and display the result topographically. In a clinical setting, the individual in question, who may have displayed a normal CT scan, is compared to an age matched/sex matched group of normals, and abnormalities are then displayed in color-mapped form, wherein bright colors show high abnormality and dull colors show insignificant abnormality. This technique provides an effective diagnostic tool.

Comparisons of Groups; Automatic Diagnosis Rules

The result of a group comparision under the system is a topographic display of statistical difference expressed as t-statistics, which when coupled with the number of degrees of freedom available in the calculation, produce a probability level of significant difference between two groups at a particular brain state. For instance, a group of normals could be compared to a group of schizophrenics by the creation of t-statistic displays with respect to a variety of brain states and stimuli. The user looks for displays which exhibit high degrees of coherence and statistical difference. This is normally shown on a screen in color. The larger statistical differences appear as brighter colors. The degree to which the differences are focused at particular points or diffused over the skull is also apparent. Smoothness in the lines dividing areas of different brightness suggests focused differences, while diffuse differences are suggested by ragged edges between dim and bright areas. It is possible for the researcher, upon selection of a particular map that shows something interesting, to save the matrix for later analysis. Such a saved matrix of t-statistics can be used to non-linearly weight the underlying data frames to create features which can be analyzed using TICAS. Once a set of saved frames representing group difference information is accumulated, he then converts all of the saved information, representing features which tend to distinguish the two groups into a file format which is suitable for analysis by TICAS, which is a multi-variate classification system, publicly available from the University of Arizona, courtesy of Dr. Peter H. Bartell.

TICAS is designed to sift through all of the features saved in the course of the inter-group analysis and pick those which prove to be the most discerning mathematically to produce a set of features which succinctly allows automatic diagnosis of a patient.

This procedure has been used to successfully discriminate between normal subjects and those with dyslexia, to discriminate between normal subjects and those with supertentorial brain tumor, and to discriminate between subjects with exposure to organophosphate compounds and nonexposed controls.

Dyslexia Analysis

An article, *Dyslexia Regional Differences in Brain Electrical Activity by Topographic Mapping*, Duffy et al. (Annals of Neurology, Vol. 7, No. 5, May, 1980), hereby incorporated by reference, describes the use of the brain electrical activity mapping system to identify the parts of the brain whose electrical activity differs for individuals suffering from reading disability (dyslexia) as compared with normal individuals, and to establish objective standards for diagnosing dyslexia. The previously described battery of brain state tests were administered to a dyslexic group and a control group. Visual and auditory stimuli were repeatedly presented to both groups and recorded with the appropriate trial markers. The stimuli were offered in pseudorandom fashion. Using the brain electrical activity mapping system, topographic displays of the alpha (8 to 11.75 Hz) and theta (4 to 7.75 Hz) activity at each electrode for each tested brain state for each subject were produced. Similar cartoons of 128 frames (4 milliseconds each) were prepared for each type of EP response for each subject. The resulting brain state frames and EP response frames for the dyslexic group and the control group were then averaged to form mean frames of each group for each state and stimulus. The two groups of mean images were then compared using the t-statistic function. A further transformation produced a matrix of percentile index values (PI) whose value is related inversely to t-values. The PI values permit a graphic localization of regions of maximum difference between the dyslexic group and the control group. By topographically displaying the PI matrices for alpha and theta for each brain state and for each EP stimulus, it was possible to identify the brain regions which differed between the dyslexics and the controls. As a final step, a new display matrix was formed which summarized the differences reflected in all of the PI matrices as indicated by the occurrence of a certain PI level on at least one of the underlying PI matrices. The map of PI differences having a value of at least 2 identified four brain areas related to dyslexia: (1) bilateral medical frontal, (2) left anteriolateral frontal, (3) left mid-temporal and (4) left posterolateral quadrant. Classic concepts of dyslexia had not suggested the involvement of all of these brain areas in dyslexics. The study also indicated that alpha brain activity was involved in dyslexia as well as the theta activity which has previously been viewed as of primary importance.

In *Dyslexia: Automated Diagnosis by Computerized Classification of Brain Electrical Activity,* Duffy et al. (Annals of Neurology, Vol. 7, No. 5, May, 1980) hereby incorporated by reference, specific highly effective diagnostic rules for identifying dyslexics were developed by a rule selection process applying TICAS software to the brain wave data derived in the study described immediately above. Working from displays of brain electrical activity, 183 features were identified for particular regions and brain states in which the strongest differences between the dyslexic group and the normal group occurred. Two of the 183 features were identified as capable of classifying unknown subjects as dyslexic or normal with a success of 80-90%.

Localization of Tumor

In *Brain Electrical Activity Mapping (B.E.A.M.); A Method for Extending the Clinical Utility of EEG and Evoked Potential Data,* Duffy, et al (Annals of Neurology, Vol. 5, No. 4, April, 1979), hereby incorporated by reference, the use of brain electrical activity mapping system topographic displays to identify the location of a brain tumor was discussed. Spectral EEG data in the four classic bands (delta, theta, alpha, and beta) was recorded for various tested brain states. Average EP response data for strobe light stimuli comprising 128 time frames of 4 milliseconds each was also recorded. After three-point linear interpolation to expand the matrix, displays of spectral EEG data, and cartooned EP data were obtained. FIG. 5 of the article illustrates the spectral EEG displays in the four classic bands of brain activity for a patient with a known tumor, which had been located by CT scanning. The assymmetries in the spectral displays also identify the area of the tumor, although the suggested lesion size was larger than indicated by CT scanning. Analysis of 7 tumor patients, whose classic EEG's were normal or non-localizing, showed that brain electrical activity mapping studies were able to define the lesions almost as effectively as CT scan.

Use of Significance Probability Mapping with B.E.A.M. to Compare Groups and Compare Individuals to Groups

In *Significant Probability Mapping: An Aid in the Topographic Analysis of Brain Electrical Activity,* Duffy et al., accepted for publication the authors describe the use of topographical displays of statistical transformations of data. In one application, EP response data was obtained from a group of subjects with brain tumors and a second control group of subjects. The data was broken into sequential frames of 4 milliseconds each. For the control group, new matrices of mean and variance of each electrode over all members of the group were prepared. A z-statistic matrix was formed for each tumor subject to illustrate his deviation from the normal population. Using the z-statistic display a clinical neurophysiologist was able to identify 11 of 12 tumor subjects.

In a second application, discussed in the same article, EEG steady-state signals were recorded for three different brain states (resting but alert with no external stimulation, listening to a tape recording of speech, and listening to a tape recording of music) for individuals in a group of dyslexics and individuals in a group of normal readers. Matrices of alpha band activity were produced for each individual, and mean and variance matrices for each state were prepared for each of the two groups. For each group t-statistic matrices were formed to compare the resting and listening to speech states and the resting and listening to music states. By examining the t-statistic displays for the two groups it was possible to infer the differences in speech-induced and music-induced brain activity between the dyslexics and the normal readers. Those determinations could not have been made from an analysis of the underlying EEG alpha matrices.

Use of Grid Sector Analysis of B.E.A.M. SPM Data to Determine Degree of Focal or Global Deviation From Normal

In an unpublished article, "Quantification of Focal Abnormalities in BEAM Data by Grid Sector Analysis: Automated discrimination Between Normal Subjects and Patients with Supratentorial Brain Tumor", Duffy, et al., describes uses of grid sector analysis as part of the brain electrical activity mapping system for the purpose of automated neurophysiological diagnosis of brain tumor. In this application, EEG and visual EP data were recorded from a group of patients with confirmed supratentarial brain tumor and from a control group. SPM matrices were prepared comparing the tumor subjects to a normal group and comparing the control group to the tumor group. Four 96 millisecond time periods of EP data were analyzed. Grid sector analyses on the data resulted in a set of 1096 combined global and focal features from the combined EEG and EP data. By a process of features selection and rule development and testing, two features were identified as most useful in distinguishing the tumor subjects from the control subjects. When classification rules developed on the initial group of 30 subjects were applied to a new group of 10 subjects, containing 5 normals and 5 subjects with brain tumor, all ten were correctly classified.

Other Embodiments

Other embodiments of the invention are within the following claims. For example, the input data may be obtained from any type of transducer capable of measuring brain electrical activity, and

topographic displays can be prepared from the signals taken from the skull, without interpolation of additional points to form a display matrix.

Related Applications

This application is related to the following applications, each of which is hereby incorporated by reference:

What is claimed is:

1. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient,

stimulus means for repeatedly providing a sensory stimulus for activating the brain to produce EP responses to said transducers,

response averaging means connected to be responsive to said transducers, to produce average responses for each transducer,

processing means connected to be responsive to said averaging means for processing said average responses to generate a time sequence of matrices,

display means connected to be responsive to said processing means, for displaying said matrices as a time sequence of topographic maps of the skull, said matrice having elements defining discrete points of said maps,

said display means including means for displaying said topographic maps at a variable frame rate, said maps corresponding to different portions of said average responses being displayed respectively at different selected frame rates.

2. The apparatus of claim 1 wherein said display means includes means for displaying maps corresponding to initial portions of said average responses at a slower rate than maps corresponding to later portions of said average responses.

3. The apparatus of claim 1 wherein said display means includes means to display said topographic maps at a frame rate that varies logarithmically.

4. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus including

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull,

processing means connected to be responsive to said transducers, for processing responses of said transducers to generate a time sequence of matrices, each of said matrices having elements representing the instantaneous amplitudes of said responses at various locations on the skull and there being a sufficient number of said matrices for a selected time period of actual brain activity for capturing onset of a transient event that occurs with a rapidity on the order of that of an epileptic spike,

said processing means including means to generate from said time sequence of matrices a running-average matrix which at any given time represents the current matrix averaged with a selected number of the matrices preceding it in time,

display means connected to be responsive to said processing means, for displaying said matrices as a time sequence of topographic maps of the skull, said elements defining discrete points of said matrice having maps,

said display means including means for displaying said topographic maps at a variable frame rate and for selectably slowing said frame rate to permit observation of said transient event.

5. The apparatus of claim 4 wherein said processing means includes means for generating 200 or more matrices for each second of real time.

6. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient,

storage means connected to be responsive to said transducers for storing responses of said transducers during first and second time periods,

processing means connected to be responsive to said transducers, for processing said responses to generate first and second matrices each having elements representing brain activity at different skull locations, said first matrix representing information on brain activity during said first period, and said second matrix representing information on brain activity during said second period,

different means connected to be responsive to said processing means, for forming a difference matrix having elements each corresponding to the difference between corresponding elements of said first and second matrices,

display means connected to be responsive to said different means, for displaying said different matrix as a topographic map of the skull, said matrix elements each forming a discrete point of said topographic map.

7. The apparatus of claim 6 further comprising stimulus means for providing a sensory stimulus to generate an EP response and wherein at least one of said first and second periods of time are during said EP response.

8. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient,

stimulus means for repeatedly generating a sensory stimulus for the brain, to produce at said transducers repeated segments of data, each said segment having a pre-stimulus response and a post-stimulus response,

response averaging means connected to be responsive to said transducers, for averaging said segments to produce average pre-stimulus and average post-stimulus responses for each transducer,

baseline means connected to be responsive to said responsive averaging means, for determining a zero baseline for said average segments from the mean level of at least a portion of the respective average pre-stimulus response, and

subtraction means connected to be responsive to said baseline means, for generating zeroed average segments by subtracting from each average segment the zero baseline determined by said baseline means,

processing means connected to be responsive to said subtraction means, for processing said zeroed average segments to generate one or more matrices, each said matrix having element representing information on the electrical activity of the brain at one location on the skull,

display means connected to be responsive to said processing means, for displaying said one or more matrices as topographic maps of the skull, said matrix elements forming discrete points of said maps.

9. The apparatus of claim 8 further comprising

means connected to be responsive to said stimulus means, for storing the time of occurrence of each said stimulus and

means connected to be responsive to said means for storing, for dividing each said segment into a predetermined pre-stimulus subinterval during which the pre-stimulus response occurs and a predetermined post-stimulus subinterval during which the post-stimulus response occurs, by using said stored times of stimuli occurrence as an indication of the boundary between said subintervals.

10. The apparatus of claim 8 wherein said processing means includes means to generate from said zeroed average segments a time sequence of said matrices, the display elements of each matrix representing the instantaneous amplitude of an EP response at various locations on said skull, and

said display means includes means for displaying said matrices in sequence, to thereby display said EP response as a time-varying topographic map.

11. The apparatus of claim 10 wherein said processing means includes means to generate said sequence of matrices in an endless loop, to thereby produce a cyclical display of said EP response.

12. The apparatus of claim 8 further comprising sampling means connected to be responsive to said transducers, for sampling and storing as a sequence of digital words said segments, and wherein said response averaging, baseline, and subtraction means all include means for performing the respective functions digitally.

13. The apparatus of claim 12 wherein said response averaging means includes

a summing buffer connected to be responsive to said sampling means, and having locations for storing each said sampled digital word for each transducer and

means connected to be responsive to said sampling means, for adding to said buffer locations new digital words corresponding to each new segment, to thereby generate said average pre- and post-stimulus responses.

14. The apparatus of claim 13 wherein said sampling means includes means for taking from 20 to 2000 equally-spaced-in-time samples of said pre-stimulus response and for taking 20 to 2000 equally-spaced-in time samples of said post-stimulus response.

15. The apparatus of claim 13 further comprising means connected to be responsive to said sampling means, for comparing said new digital words to predetermined limits and rejecting digital words falling outside said limits, thereby not adding said words to said buffer locations.

16. The apparatus of claim 12 further comprising means connected to be responsive to said transducers, for filtering high-frequency components from the post-stimulus response for any selected transducer by multipoint interpolation of the digital words for the selected response.

17. The apparatus of claim 8 wherein said baseline means includes means for selectively eliminating from the mean level computation portions of an average pre-stimulus response for a selected transducer, to thereby provide a more accurate baseline for the response of the selected transducer.

18. The apparatus of claim 8 further comprising means connected to be responsive to said baseline means, for displaying said pre-stimulus and post-stimulus responses and said baseline for a selected transducer, to permit an operator to evaluate the appropriateness of said baseline.

19. The apparatus of claim 8 wherein

said baseline means includes means for calculating the root mean square average value of the average pre-stimulus response and of the average post-stimulus response and

said display means includes means for displaying said root mean square average values along with said responses,

whereby such root mean square value can be used in connection with said displayed responses to evaluate whether the noise level in the responses for any particular transducer is unacceptably large and for thereby determining whether new data should be taken.

20. The apparatus of claim 8 or 19 further comprising means connected to be responsive to said baseline means, for an operator to adjust the baseline value up or down for any selected transducer average response.

21. The apparatus of claim 8, 18, or 20 further comprising means connected to be responsive to said baseline means, for repeating the steps of calculating said baseline and viewing said responses for selected transducers, whereby adjustments can be made to said baseline until said responses are satisfactory.

22. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient or measure the EEG response at said locations,

sampling means connected to be responsive to said transducers, for sampling said EEG responses during time intervals shorter than the anticipated interval between interruptions in the state of brain activity,

spectral processing means connected to be responsive to said sampling means, for computing, for each of said transducers, the Fourier transforms of the sampled EEG responses and for computing from said Fourier transforms, for each of said transducers, the spectral energy contained in selected frequency bands,

processing means connected to be responsive to said spectral processing means, for processing the output of said spectral processing means to generate a plurality of matrices, one said matrix for each selected frequency band, each said matrix having elements each of which represents the spectral energy within the respective frequency band at one location on the skull,

display means connected to be responsive to said processing means, for displaying said matrices as topographic maps of the skull, said matrix elements forming discrete points of said maps.

23. The apparatus of claim 22 wherein said sampling means is arranged for sampling and storing as a sequence of digital words selected portions of said EEG responses, and wherein said spectral processing means includes means for digitally performing said Fourier transform determination.

24. The apparatus of claim 23 wherein said sampling means includes means to sample said EEG responses at at least 3 times the highest frequency in said selected frequency bands.

25. The apparatus of claim 24 wherein said sampling means includes means to sample said EEG responses at from 4 to 5 times said highest frequency.

26. The apparatus of claim 22 wherein said sampling means includes marking means for storing the start and stop times of a particular brain activity.

27. The apparatus of claim 22 wherein a time maximum interval for sampling said EEG responses is on the order of two seconds.

28. The apparatus of claim 22 wherein said sampling time interval of said EEG responses is from 0.1 to 4.0 seconds long.

29. The apparatus of claim 22 further comprising averaging means connected to be responsive to said spectral processing means, for averaging said Fourier transforms to generate, for each transducer, the average spectral energy contained within said frequency bands.

30. The apparatus of claim 22 wherein said frequency bands comprise the alpha, beta, delta, and theta bands.

31. The apparatus of claim 22 further comprising filtering means connected to be responsive to said transducers, for removing from said EEG responses frequency components outside the prominent frequency bands of brain electrical activity.

32. The apparatus of claim 31 wherein said filtering means includes means for removing from said EEG responses at least frequency components below 0.5 Hz and above 50 Hz.

33. The apparatus of claim 31 wherein said filtering means includes means for removing from said EEG responses at least frequency components below 0.5 Hz and above 1000 Hz.

34. The apparatus of claim 31 wherein said filtering means includes means for removing from said EEG responses at least frequency components below 300 Hz and above 5000 Hz.

35. The apparatus of claim 22 wherein said spectral processing means includes means for tapering the beginning and end portions of said responses prior to determination of the Fourier transform to reduce high frequency artifacts.

36. Apparatus for generating a topographic display of information of the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient:

processing means connected to be responsive to said transducers, for processing electrical responses measured at said transducers, said processing means including means for generating one or more matrices, each matrix containing a plurality of elements, said elements representing information on the electrical activity of the brain at particular skull locations,

statistical processing means connected to be responsive to said processing means, for processing at least two said matrices to generate a statistical comparison matrix having elements, each element being representative of a statistical difference between the corresponding elements in said two matrices,

display means connected to be responsive to said statistical processing means, for displaying said statistical comparison matrix as a topographic map of the skull, said matrix element forming discrete points of said map.

37. The apparatus of claim 36 further comprising interpolation means connected to be responsive to said statistical processing means, for expanding said statistical comparison matrix to a larger matrix prior to display, and larger matrix having additional statistical comparison elements for skull locations intermediate said transducer locations, said additional elements being generated by interpolation from the elements of said statistical comparison matrix.

38. The apparatus of claim 36 further comprising interpolation means connected to be responsive to said processing means, for expanding said matrices to larger matrices prior to said statistical processing, said larger matrices having additional elements for skull locations intermediate said transducer locations, said additional elements being generated by interpolation from the elements of said matrices.

39. The apparatus of claim 36 wherein said statistical processing means includes means to generate as said statistical comparison matrix a matrix of t values representing the statistical difference between a first and a second group of matrices, each group having matrices having a plurality of elements.

40. The apparatus of claim 39 wherein said statistical processing means includes

means connected to be responsive to said means to generate a matrix of t values, for generating a first mean-value matrix having elements which are representative of the mean values of the respective elements the matrices said first group,

means connected to be responsive to said means to generate a matrix of t values, for generating a first standard-deviation matrix having elements which are representative of the standard deviations of the respective elements of the matrices of said first group,

means connected to be responsive to said means to generate a matrix of t values, for generating a second mean-value matrix having elements which are representative of the mean values of the respective elements of the matrices of said second group,

means connected to be responsive to said means to generate a matrix of t values, for generating a second standard-deviation matrix having elements which are representative of the standard deviations of the respective elements of the matrices of said second group,

means connected to be responsive to said means to generate a matrix of t values, for generating said matrix of t values from said first and second mean-value matrices and said first and second standard-deviation matrices.

41. The apparatus of claim 36 wherein said statistical processing means includes means to generate as said statistical comparison matrix a matrix of z values representing the statistical difference between one matrix and a group of matrices.

42. The apparatus of claim 41 wherein said statistical processing means includes

means connected said means to generate a matrix of z values, for generating a first matrix representative of the mean of said group of matrices,

means connected said means to generate a matrix of z values, for generating a second matrix representative of the standard deviation of said group of matrices,

said matrix of z values being generating from said one matrix and said first and second matrices, each of said matrices having a plurality of elements.

43. The apparatus of claim 42 wherein said first matrix is representative of the mean of a normalized reference population, said second matrix is representative of the standard deviation of said population, and the elements of said matrix of z values are thereby representative of the number of standard deviations by which the elements of said one matrix differ from the mean of said population.

44. The apparatus of claim 36 further comprising

means connected to be responsive to said statistical processing means, for producing from said statistical comparison matrix one or more quantitative features which are each determined by processing the elements within selected regions of said statistical matrix,

means connected to be responsive to said means for producing features, for determining a statistical merit value for selected features,

means for determining how to combine said features to form decision rules, and

means connected to be responsive to said means for determining, for classifying individuals using said decision rules.

45. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient,

statistical processing means connected to be responsive to said transducers, for processing responses at said electrical-activity transducers to generate a coefficient-of-variance matrix, said matri having element each of which represents the normalized standard deviation of the responses at one skull location, the normalized standard deviation being the standard deviation divided by the mean,

display means connected to be responsive to said statistical processing means, for displaying said coefficient-of-variance matrix as a topographic map of the skull, thereby providing a map of the level of variation in brain activity.

46. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient,

processing means connected to be responsive to said transducers, for generating from responses measured at said transducers a time sequence of first matrices, each said first matrices having display elements representing the instantaneous response at various locations on said skull,

temporal interpolation means connected to be responsive to said processing means, for generating by interpolation second matrices interspersed in said sequence of first matrices, said second matrices having elements representing the approximate response at instants of time intermediate the instants of time associated with said first matrices,

display means connected to be responsive to said processing means, for displaying said first matrices and said interspersed second matrices as a time sequence of topographic maps of the skull, said matrix elements forming discrete points of said maps, said second matrices enhancing the visual smoothness of the transitions over time between said first matrices.

47. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient,

processing means connected to be responsive to said transducers, for generating one or more matrices from the responses measured at said transducers, each matrix having elements representing information on electrical activity of the brain at one location on the skull,

display means connected to be responsive to said processing means, for displaying said matrices as topographic maps of the skull, said matrix elements forming discrete points of said maps,

waveform quality control means for previewing said transducer responses or processed versions thereof, said quality control means including at least two of the following means

means for tagging a response with information on its waveform quality, including an indication of whether the response should be used in later processing,

means at the discretion of the operator for eliminating a response from further processing,

means for automatically eliminating a response from further processing if a portion thereof exceeds a predetermined threshold,

means for smoothing a response to eliminate undesired high frequency components,

means for adjusting a zero baseline of a response, said zero baseline having been previously set automatically,

means for eliminating selected portions of a response from further processing, and

means for displaying in numerical form the value of a response at a point in time selected by the operator.

48. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient,

means connected to be responsive to said transducers, for sampling responses measured at said transducers and storing the sampled responses as a series of data matrices, one matrix for each sampling time,

means connected to be responsive to said means for sampling, for selectively viewing the sampled responses corresponding to a single transducer as a plot of transducer output versus time,

quality control means for adjusting portions of said selectively viewed responses or eliminating said responses from further processing,

processing means connected to be responsive to said means for sampling, for processing said data matrices to generate one or more processed matrices, said processed matrices having elements each corresponding to one transducer location,

interpolation means connected to be responsive to said processing means, for generating expanded matrices by expanding the number of elements in said processed matrices to provide elements corresponding to skull locations intermediate said transducer locations,

display means connected to be responsive to said interpolation means, including a video monitor capable of generating a matrix of grey tones for displaying said expanded matrices as topographic maps of the skull, said expanded matrices having elements defining the grey tones of discrete points on said maps.

49. The apparatus of claim 48 further comprising matrix storage means connected to be responsive to said means for sampling, processing means, and interpolation means, for tagging selected data, processed, or expanded matrices and storing them for later recall and processing.

50. The apparatus of claim 48 further comprising means connected to be responsive to said transducers, for storing calibration responses from said transducers and means for calibrating said responses matrices by determining from said stored calibration responses a DC offset and gain for each said transducer.

51. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient,

processing means connected to be responsive to said transducers, for processing responses measured at said transducers to generate one or more matrices, each matrix having elements representing information on brain activity at different skull locations,

display means connected to be responsive to said processing means, for displaying said one or more matrices as topographic maps of the skull, said matrix elements forming discrete points of said maps, said display means including a video monitor which generates a visible grey tone at each said discrete point, said tone being variable from a maximum tone to a minimum tone, and

scaling means connected to be responsive to said processing means, for scaling said matrix elements to the available tones.

52. The apparatus of claim 51 wherein

said video monitor generates a zero tone intermediate said maximum and minimum tone and

said scaling means comprises at least two of the following means

means connected to be responsive to said processing means, for scaling the maximum matrix element to the maximum tone and the minimum matrix element to the minimum tone and linearly interpolating inbetween,

means connected to be responsive to said processing means, for scaling the maximum matrix element to the maximum tone and the minimum matrix element to the zero tone and linearly interpolating inbetween,

means connected to be responsive to said processing means, for scaling the maximum matrix element to an operator supplied tone,

means connected to be responsive to said processing means, for scaling the minimum matrix element to an operator supplied tone,

means connected to be responsive to said processing means, for excluding from the scaling operation selected unusually high or low valued matrix elements and for assigning to matrix elements that fall outside the available tone range the closer of the maximum or minimum tone.

53. The apparatus of claim 51 wherein said video monitor generates colored grey tones of a first and a second color, with grey tones of said first color forming said grey tones between said maximum tone and said zero tone, with grey tones of said second color forming said grey tones between said minimum tone and said zero tone, and with the absence of a color tone forming said zero tone.

54. The apparatus of claim 53 wherein said two colors are complementary colors.

55. The apparatus of claim 53 wherein there are at least 6 grey tones of each of said two colors.

56. The apparatus of claim 51 wherein there are a plurality of said matrices to be displayed and said scaling means includes means for independently performing said tone scaling for each matrix displayed.

57. The apparatus of claim 51 wherein there are a plurality of said matrices to be displayed and said scaling means includes means for scaling with respect to the display elements in all said matrices so that the scaling remains the same for each matrix displayed.

58. The apparatus of claim 51 further comprising preview means connected to be responsive to said transducers, for viewing selected segments of the transducer responses and for tagging selected segments for exclusion from the scaling operation and wherein said scaling means includes means for identifying the presence of said tagging and for excluding data so tagged from said scaling operation.

59. Apparatus for generating a topographic display of information on the electrical activity of the brain, said apparatus comprising

a plurality of electrical-activity transducers adapted to be placed at spaced apart locations on the skull of a patient,

processing means connected to be responsive to said transducers, for processing responses measured at said transducers to generate one or more matrices, each matrix having elements representing information on brain activity at different skull locations,

display means connected to be responsive to said processing means, for displaying said one or more matrices as a topographic map of the skull, said matrix elements forming discrete points of said map, said display means including a video monitor which generates a tone at each said discrete point, said tone varying from a maximum tone to a minimum tone, normalizing means connected to be responsive to said processing means, for normalizing said matrix elements to a selected value, and

scaling means connected to be responsive to said processing means, for scaling said matrix elements to the available tones, said scaling means including means for assigning a selected tone to said selected normalization value.

60. The apparatus of claim 59 wherein said normalizing means includes means for normalizing said matrix elements to the matrix element representing brain electrical activity at the vertex.

61. The apparatus of claim 59 wherein said normalizing means includes means for normalizing each individual matrix element to the root mean square value of the background electrical activity at the skull location represented by the individual matrix element.

62. The apparatus of claim 59 wherein said normalizing means includes means for normalizing said matrix elements to the average root mean square value of the background electrical activity over all skull locations.

63. The apparatus of claim 59, 60, 61 or 62 further comprising

stimulus means for repeatedly providing a sensory stimulus for the brain, to produce repeated EP responses at said transducers,

response averaging means connected to be responsive to said transducers, for averaging said repeated responses for each transducer to produce an average response for each transducer, and

wherein said processing means includes means for generating from said average responses a time sequence of said matrices, and

said display means includes means for displaying said matrices in sequence.

64. The apparatus of claim 59 wherein

there is further provided spectral processing means connected to be responsive to said transducers, for computing the Fourier transforms of the responses measured by said electrical-activity transducers and for computing from said Fourier transforms the spectral energy contained in selected frequency bands,

said processing means includes means for processing the output of said spectral processing means to generate a plurality of matrices, one said matrix for each selected frequency band, each matrix having elements representing the spectral energy within the selected frequency band at various locations on the skull, and

said normalizing means includes means to normalize said matrix elements either to the total spectral energy for all said frequency bands at the skull location corresponding to said matrix element or to the average total spectral energy for all said frequency bands for all matrix elements.

65. The apparatus of claim 1, 4, 6, 8, 22, 45, 46, 47, 48, 51, or 59 wherein said processing means includes interpolation means for generating by interpolation additional matrix elements for skull locations intermediate the locations of said transducers.

66. The apparatus of claim 65 wherein said interpolation means includes means for computing the values of said additional matrix elements by three point interpolation from the values associated with the three closest transducer locations.

67. The apparatus of claim 66 wherein said three point interpolation is linear.

68. The apparatus of claim 1, 4, 6, 8, 22, 36, 45, 46, 47, 48, 51, or 59 wherein the number of said electrical-activity transducers is in the range of 10 to 200 and the number of elements in said topographic maps is at least 5 times the number of transducers.

69. A method for generating a topographic display of information on the electrical activity of the brain, said method comprising the steps of

placing a plurality of electrical-activity transducers at spaced apart locations on the skull of a patient,

storing responses of said transducers during first and second time periods,

processing said responses to generate first and second matrices each having elements representing brain activity at different skull locations, said first matrix representing information on brain activity during said first period, and said second matrix representing information on brain activity during said second period,

forming a difference matrix having elements each corresponding to the difference between corresponding elements of said first and second matrices, and

displaying said difference matrix as a topographic map of the skull, said matrix elements each forming a discrete point of said topographic map.

70. The method of claim 69 further comprising the step of providing as a stimulus for the brain during said first period a source of patterned light and providing as a stimulus for the brain during said second period a source of nonpatterned light.

71. A method of generating a topographic display of information on the EP response of the brain, said method comprising the steps of:

placing a plurality of electrical-activity transducers at spaced apart locations on the skull of a patient,

repeatedly providing a sensory stimulus for the brain so as to produce at said transducers repeated segments of data, each segment including a prestimulus response and a post-stimulus response,

averaging the repeated segments to produce an average segment for each transducer,

determining a zero baseline for each average segment from the mean level of at least a portion of the average pre-stimulus response,

subtracting the zero baselines from the respective average segments to produce zeroed average segments,

processing the zeroed average segments to generate one or more matrices of elements, with each matrix element representing information on the EP response at one location on the skull, and

displaying said one or more matrices as topographic maps of the skull, with each display point forming a discrete point on said maps.

72. A method for generating a topographic display of information on the electrical activity of the brain, said method comprising the steps of

placing a plurality of electrical-activity transducers at spaced apart locations on the skull of a patient,

repeatedly providing a sensory stimulus for activating the brain to produce EP responses at said transducers,

averaging said responses to produce average responses for each transducer,

processing said average responses to generate a time sequence of matrices, displaying said matrices as a time sequence of topographic maps of the skull, said matrices having elements defining discrete points of said maps, and

displaying said topographic maps at a variable frame rate,

maps corresponding to different portions of said average responses being displayed respectively at different selected frame rates.

73. A method for generating a topographic display of information on the electrical activity of the brain, said method including the steps of

placing a plurality of electrical-activity transducers at spaced apart locations on the skull,

processing responses of said transducers to generate a time sequence of matrices, each said matrix having elements representing the instantaneous amplitudes of said responses at various locations on the skull and there being a sufficient number of said matrices for a selected time period of actual brain activity for capturing onset of a transient event that occurs with a rapidity on the order of that of an epileptic spike,

generating from said time sequence of matrices a running-average matrix which at any given time represents the current matrix averaged with a selected number of the matrices preceding it in time,

displaying said matrices as a time sequence of topographic maps of the skull at a variable frame rate, each running-average matrix having elements defiring discrete points of said maps, and

selectably slowing the frame rate at which said topographic maps are displayed so as to permit observation of said transient event.

74. A method for generating a topographic display of information on the electrical activity of the brain, said method comprising the steps of

placing a plurality of electrical-activity transducers at spaced apart locations on the skull of a patient to measure the EEG response at said locations,

sampling the EEG responses during time intervals shorter than the anticipated interval between interruptions in the state of brain activity,

computing, for each of said transducers, the Fourier transforms of the sampled EEG responses and computing from said Fourier transforms, for each of said transducers, the spectral energy contained in selected frequency bands,

processing said computed spectral energy of said selected frequency bands to generate a plurality of matrices, one said matrix for each selected frequency band, said matrices having elements representing the spectral energy within the respective frequency band at one location on the skull, and

displaying said matrices as topographic maps of the skull, said matrix elements forming discrete points of said maps.

75. A method for generating a topographic display of information on the electrical activity of the brain, said method comprising the steps of

placing a plurality of electrical-activity transducers at spaced apart locations on the skull of a patient,

processing electrical responses measured at said transducers, said processing means including means for generating one or more matrices, each matrix containing a plurality of elements, said elements representing information on the electrical activity of the brain at particular skull locations,

processing at least two said matrices to generate a statistical comparison matrix said statistical comparison matrix having elements each of which representative of a statistical difference between the corresponding elements in said two matrices, and

displaying said statistical comparison matrix as a topographic map of the skull, said matrix elements forming discrete points of said map.

76. A method for generating a topographic display of information on the electrical activity of the brain, said method comprising the steps of

placing a plurality of electrical-activity transducers at spaced apart locations on the skull of a patient,

statistically processing responses at said electrical-activity transducers to generate a coefficient-of-variance matrix, said matrix having elements each of which represents the normalized standard deviation of the responses at one skull location, the normalized standard deviation being the standard deviation divided by the mean,

displaying said coefficient-of-variance matrix as a topographic map of the skull, thereby providing a map of the level of variation in brain activity.

77. A method for generating a topographic display of information on the electrical activity of the brain, said method comprising the steps of

placing a plurality of electrical-activity transducers for placement at spaced apart locations on the skull of a patient,

generating from responses measured at said transducers a time sequence of first matrices, each said first matrix having display elements representing the instantaneous response at various locations on said skull,

generating by interpolation second matrices interspersed in said sequence of first matrices, said second matrices having elements representing the approximate response at instants of time intermediate the instants of time associated with said first matrices,

displaying said first matrices and said interspersed second matrices as a time sequence of topographic maps of the skull, said matrix elements forming discrete points of said maps, said second matrices enhancing the visual smoothness of the transitions over time between said first matrices.

78. A method for generating a topographic display of information on the electrical activity of the brain, said method comprising the steps of

placing a plurality of electrical-activity transducers at spaced apart locations on the skull of a patient,

generating one or more matrices from responses measured at said transducers, each matrix having elements representing information on the electrical activity of the brain at one location on the skull,

displaying said one or more matrices as topographic maps of the skull, said matrix elements forming discrete points of said maps,

previewing said transducer responses or processed versions thereof, said previewing including at least two of the following steps

tagging a response with information on its waveform quality, including an indication of whether the response should be used in later processing,

eliminating a response from further processing at the discretion of the operator, automatically eliminating a response from further processing if a portion thereof exceeds a predeterminedthreshold,

smoothing a response to eliminate undesired high frequency components,

adjusting a zero baseline of a response, said zero baseline having been previously set automatically

eliminating selected portions of a response from further processing, and

displaying in numerical form the value of a response at a point in time selected by the operator.

79. A method for generating a topographic display of information on the electrical activity of the brain, said method comprising the steps of

placing a plurality of electrical-activity transducers at spaced apart locations on the skull of a patient,

sampling responses measured at said transducers and storing the sampled data as a series of data matrices, one matrix for each sampling time,

selectively viewing the sampled data corresponding to a single transducer as a plot of transducer output versus time,

adjusting portions of said selectively viewed data or eliminating said data from further processing,

processing said data matrices to generate one or more processed matrices said one or more processed matrices having elements each corresponding to one transducer location,

expanding the number of elements in said one or more processed matrices to provide elements corresponding to skull locations intermediate said transducer locations,

providing a video monitor capable of generating a matrix of grey tones for displaying said expanded matrices as topographic maps of the skull, said expanded matrix elements defining the grey tones of discrete points on said maps.

80. A method for generating a topographic display of information on the electrical activity of the brain, said method comprising the steps of

placing a plurality of electrical-activity transducers at spaced apart locations on the skull of a patient,

processing responses measured at said transducers to generate one or more matrices, each matrix having elements representing information on brain activity at different skull locations,

displaying one or more said matrices as topographic maps of the skull, said matrix elements forming discrete points of said maps,

providing a video monitor which generates a visible grey tone at each said discrete point, said tone being variable from a maximum tone to a minimum tone, and

scaling said matrix elements to the available tones.

81. The method of claim 80 wherein

said providing step comprises providing a said video monitor which generates a zero tone intermediate said maximum and minimum tone, and

said scaling step comprises at least two of the following steps

scaling the maximum matrix element to the maximum tone and the minimum matrix element to the minimum tone and linearly interpolating inbetween,

scaling the maximum matrix element to the maximum tone and the minimum matrix element to the zero tone and linearly interpolating in between,

scaling the maximum matrix element to an operator supplied tone,

scaling the minimum matrix element to an operator supplied tone,

excluding from the scaling operation selected unusually high or low valued matrix elements and assigning to matrix elements that fall outside the available tone range the closer of the maximum or minimum tone.

82. A method for generating a topographic display of information on the electrical activity of the brain, said method comprising the steps of

placing a plurality of electrical-activity transducers at spaced apart locations on the skull of a patient,

processing responses measured at said transducers to generate one or more matrices, each matrix having elements representing information on brain activity at different skull locations,

displaying said one or more matrices as a topographic map of the skull, said matrix elements forming discrete points of said map,

providing a video monitor which generates a tone at each said discrete point, said tone varying from a maximum tone to a minimum tone,

normalizing said matrix elements to a selected value, and

scaling said matrix elements to the available tones, said scaling means including means for assigning a selected tone to said selected normalization value.

[57] **ABSTRACT**

A method having applicability in replication of desired consciousness states; in the training of an individual to replicate such a state of consciousness without further audio stimulation; and in the transferring of such states from one human being to another through the imposition of one individual's EEG, superimposed on desired stereo signals, on another individual, by inducement of a binaural beat phenomenon.

METHOD OF INDUCING MENTAL, EMOTIONAL AND PHYSICAL STATES OF CONSCIOUSNESS, INCLUDING SPECIFIC MENTAL ACTIVITY, IN HUMAN BEINGS

BACKGROUND OF THE INVENTION

The present invention relates to a method of inducing various states of consciousness in human beings. More particularly, the invention relates to a method of inducing such states of consciousness through generation of stereo audio signals having specific wave shapes which act as a carrier of a binaural beat. The resultant binaural beat acts to entrain brain waves into unique waveforms characteristic of identified states of consciousness. The invention is applicable in areas of learning and behavior replication as well as in the area of sleep inducement, and thus represents a significant departure from and improvement over known audio-based sleep inducement techniques, some of which will be discussed below.

The binaural beat phenomenon was discovered in 1839 by H. W. Dove, a German experimenter. Generally, this phenomenon works as follows. When an individual receives signals of two different frequencies, one signal to each ear, the individual's brain detects a phase difference or differences between these signals. When these signals are naturally occurring, the detected phased difference provides directional information to the higher centers of the brain. However, if these signals are provided through speakers or stereo earphones, the phase difference is detected as an anomaly. The resulting imposition of a consistent phase difference between the incoming signals causes the binaural beat in an amplitude modulated standing wave, within each superior olivary nucleus (sound processing center) of the brain. It is not possible to generate a binaural beat through an electronically mixed signal; rather, the action of both ears is required for detection of this beat.

FIGS. 1A and 1B show two superposed waves of different frequencies. FIG. 1C shows the resulting wave, which has a clear beat phenomenon. Assuming the two waves have equal amplitude but different respective frequencies f_1, f_2, the combination of the two waves may be represented mathematically as follows:

$$\begin{aligned} X &= X_1 + X_2 \\ &= a^*\cos(2\pi f_1 t) + a^*\cos(2\pi f_2 t) \\ &= a^*[\cos(2\pi f_1 t) + a^*\cos(2\pi f_2 t)] \\ &= 2a^*\cos\left(2\pi \frac{[f_1 - f_2]}{2}\, t\right)^*\cos\left(2\pi \frac{[f_1 + f_2]}{2}\, t\right) \end{aligned}$$

The beat phenomenon arises from the variation in amplitude of a resulting carrier frequency. Pulses appear every $\frac{1}{2}(f_1-f_2)$, with two maxima occurring each cycle, when $\cos(2\pi)\frac{1}{2}[f_1-f_2]=\pm 1$. That is, the beat frequency is simply f_1-f_2, a result which agrees with experience.

Known consciousness state inducing techniques have not used this binaural beat phenomenon, but have relied on other techniques, as follows. For example the use of audio generators to induce a state of consciousness known as sleep is well known in the prior art, as exemplified by U.S. Pat. No. 2,711,165 and 3,384,074. In one type of technique exemplified in these patents, generated audio signals include pleasing and harmonious study sounds or vibrations, fixed frequency signals which are buried cyclically with respect to amplitude, and repetitive sounds such as the falling of rain on the roof and the sighing wind through the trees.

U.S. Pat. No. 2,304,095 relates to a method of inducing sleep by generation of an audible or tactual signal which is related to the physiological process of heartbeat and respiration. In the disclosed method, the pitch and amplitude of a pleasing audio signal are varied at a rate somewhat slower than either the rate of heartbeat or the rate of respiration. As a result, heartbeat and respiration tend to synchronize with the audio signal, thus lowering heartbeat and respiration rates and inducing sleep.

Of course, there are other naturally-occurring sounds which have been recorded, and which are not varied, but which instead induce a state of relaxation which leads to sleep for a similar reason. For example, the pounding of waves on a shore line occurs at a frequency generally lower than that of heartbeat or respiration, and induces a state of relaxation.

The use of an electroencephalogram (EEG) as a research and diagnostic tool has led to findings that particular brain wave patterns are indicative of different states of consciousness. In 1934, researchers discovered that brain waves, and their associated states of consciousness, could be altered with repetitive visual stimulation at a known frequency, an effect known as entrainment. Scientific interest in entrainment continued throughout the 1960's. In the 1970's, numerous independent studies repeatedly confirmed that rhythmic flashing lights rapidly entrained brain waves.

A sonic equivalent of photic entrainment also is known, as disclosed for example in commonly-assigned U.S. Pat. No. 3,884,218, the inventor of which is the inventor of the present application. This patent discloses a method of inducing sleep in a human being by generating an audio signal which is made up of a familiar pleasing repetitive sound modulated by frequencies usually associated with an EEG sleep pattern. There are different EEG patterns related to various levels or depths of sleep, and it has been found that by modulating the repetitive sound with these different sleep patterns, it is possible to induce various levels of sleep. The inventor has coined the term frequency following response, or FFR, to describe this phenomenon.

Other known techniques for inducing various states of consciousness, or for performing brainwave analysis and related functions, are shown, for example, in the following U.S. patents:

2,466,054	4,034,741	3,160,159	4,141,344
3,576,185	4,227,516	3,712,292	4,335,710
3,753,433	4,573,449	3,826,243	4,834,701
3,837,331.			

The binaural beat phenomenon described above also can create a frequency entrainment effect. If a binaural beat is within the range of brain wave frequencies, generally less than 30 cycles per second, the binaural beat will become an entrainment environment. This effect has been used to study states of consciousness, to improve therapeutic intervention techniques, and to enhance educational environments. However, the modulation of the binaural beat signals with brain waves associated with particular activities has not been attempted previously.

SUMMARY OF THE INVENTION

In view of the foregoing, it is one object of the invention to provide a method of inducing states of consciousness by generating stereo audio signals having specific wave shapes. These signals act as a carrier of a binaural beat. The resulting beat acts to entrain brain waves into unique waveforms characteristic of identified states of consciousness.

The method of the invention extends beyond the confines of the frequency entraining concept, and incorporates waveform entrainment by altering the wave shape of the binaural beat. Conventional binaural beat frequency entrainment previously has been limited to conventional wave shapes, i.e., square triangular sinusoidal, or in some cases, the various musical instruments. For example, it is known that radiant energy, such as sound in this case, may be defined by its frequency, amplitude, and wave shape. A musical note is a particularly suitable example of this. Generally, the musical note A above middle C in the twelve tone diatonic scale is assigned a frequency of 440 cycles per second. The amplitude of that note is expressed as the loudness of the signal. However, the wave shape of that note is related strongly to the instrument used. An A played on a trumpet is quite different from an A played on a violin.

The similarity results from the distinct shapes of the waveforms of each instrument. Similarly, human brain waves also have unique wave shapes, wave contours which are neither sinusoidal, nor square, nor triangular, nor like those of any musical instrument.

In accordance with the invention, human brain waves, in the form of EEGs, are superimposed upon specific stereo audio signals, known as carrier frequencies which are within the range of human hearing. Thus the invention relates not only to techniques of generating the binaural beat, but also to specific waveforms of the binaural beat in frequency, waveshape, and amplitude, and most particularly to the source of the data used to produce such waveforms.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1A–1C show two waves at different frequencies, and the resulting binaural beat, respectively;

FIGS. 2A–2D show an input wave, two stereo carrier waves as determined by Fourier analysis, and the resultant binaural beat wave, which matches the contour of the input wave;

FIGS. 3A–3B, 3C–3D, 3E–3F, and 3G–3H are pairs of graphs showing a normal waking EEG and FFR responses in different signal ranges, respectively; and

FIGS. 4A–4F show topographic brain maps of the neocortex of a subject in a normal waking state, and after listening to a binaural beat sound pattern.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

As will be discussed below, different regions of the brain produce distinct electrical waveforms during various physical, mental, and emotional states of consciousness. In the method of the invention, binaural beat audio wave shapes are made to match such particular brain waves as they occur during any mental physical, and emotional human condition of consciousness. Thus, it is possible to convert waveforms from specific brain regions, as well as complete brain surface electrical topography.

In the audio application of the invention, using sampled EEG waveforms from a subject in specific states of consciousness and activity, mental and/or physical, these waveforms are impressed upon multiple sets of sound carrier waves within the human spectrum of hearing. Thus, the waveforms translate into wave amplitude modulations of the carrier to effect what is called a frequency following response, or FFR, as mentioned above.

Some description of the empirical procedure used in the course of developing the invention will be useful, as background. In the 1970s, testing was done on various subjects for effective EEG frequencies using audio signals as a human stimulus. Such frequencies were replicated as amplitude modulation of single-channel audio signals within human hearing ranges, for use in sleep-inducing, attention-focusing, etc.

Where particular subjects responded especially well, those signals were converted to binaural beat patterns. The binaural beat signals were derived by first selecting frequencies of the single-channel audio signals based on the well-known "Oersted Curve", named after the famous 19th century physicist. Using this curve permitted selection of specific audio frequencies to provide the greatest binaural beat frequencies at a much lower range. The effectiveness of the tests were doubled as a result of using binaural beat signals.

In the mid 1980s, EEG waveforms themselves were examined as produced by the binaural signals employed. FFR and entrainment factors thought to be responsible for success were verified. One of the results identified as the probable cause of such effectiveness was the synchronization of the brain hemispheres in such signal frequency ranges (i.e. the induced signals were present simultaneously in major portions of both brain hemispheres).

Experimentation expanded to different subjects in similar states of consciousness. Isolation of EEG patterns in these states of consciousness, and conversion of these patterns to binaural sound, with subsequent reapplication of the binaural sounds produced significantly enhanced results. The effect was especially apparent among naive subjects.

Recently, EEG neuromapping began of subjects with particular talents, where those subjects could utilize those talents (e.g. playing a piano sonata, or solving a mathematical equation) at a mental or visualization level. It was possible to isolate the EEG waveforms related to utilization of those talents, and to convert those waveforms to binaural sound. Subsequent exposure of the subject to such patterns enhanced the individual's ability to replicate the process. Exposing other subjects to the signals produced a learned response through repetition.

Thus, the inventor believes that the inventive process, while not necessarily creating a musician or a mathematician, will set up an EEG ambiance in which learning will be facilitated.

Looking more closely now at the implementation and effects of the invention, FIGS. 2A–2D show a phenomenon wherein an input brain wave signal from a particular brain region is superimposed on stereo carrier waves. FIG. 2D shows the resultant binaural beat wave which matches the contour of the input wave.

The generation and propagation of the binaural beat may be understood from the following series of equations, based on the following.

9(

taking the components from FIGS. 1A-1C, and scaling each component to an appropriate factor (say, α and β).

These components could be recombined to form a beat in accordance with the original components. Linearity and orthogonality principles make these manipulations possible. First, assign the measured wave to be the beat frequency, x.

$$x=\alpha-\beta$$

From the beating waves discussed with respect to FIGS. 1A-1C:

$$\sin(\alpha)+\sin(\beta)=2\cos\left(\frac{\alpha-\beta}{2}\right)\sin\left(\frac{\alpha+\beta}{2}\right)=$$

$$2\cos\left(\frac{x}{2}\right)\sin\left(\frac{2\alpha-x}{2}\right)$$

$$\cos(\alpha)+\cos(\beta)=2\cos\left(\frac{\alpha-\beta}{2}\right)\cos\left(\frac{\alpha+\beta}{2}\right)=$$

$$2\cos\left(\frac{x}{2}\right)\cos\left(\frac{2\alpha-x}{2}\right)$$

Now, let us alter the Fourier series f(x) to produce the beat in the shape of the original wave, f'(x):

$$f(x)=\frac{1}{2}a_0+\frac{1}{2}\sum_{n=1}^{\infty}\cos\left(\frac{nx}{2}\right)\left[a_n\cos\left(n\frac{2\alpha-x}{2}\right)-b_n\sin\left(n\frac{2\alpha-x}{2}\right)\right]\Bigg)$$

$$=\frac{1}{2}a_0+\frac{1}{2}\sum_{n=1}^{\infty}\cos\left(n\frac{\alpha-\beta}{2}\right)\left[a_n\cos\left(n\frac{\alpha+\beta}{2}\right)+b_n\sin\left(n\frac{\alpha+\beta}{2}\right)\right]\Bigg)$$

$$=\frac{1}{2}a_0+\frac{1}{2}\sum_{n=1}^{\infty}\cos\left(n\frac{\alpha-\beta}{2}\right)a_n\cos\left(n\frac{\alpha+\beta}{2}\right)+\cos\left(n\frac{\alpha-\beta}{2}\right)b_n\sin\left(n\frac{\alpha+\beta}{2}\right)\Bigg]\Bigg)$$

$$=\frac{1}{2}a_0+\frac{1}{2}\sum_{n=1}^{\infty}a_n[\cos(\alpha)+\cos(\beta)]+b_n[\sin(\alpha)+\sin(\beta)])$$

$$=\frac{1}{4}a_0+\frac{1}{2}\sum_{n=1}^{\infty}[a_n\cos(\alpha)+b_n\sin(\alpha)]+\frac{1}{4}a_0+\frac{1}{2}\sum_{n=1}^{\infty}[a_n\cos(\beta)+b_n\sin(\beta)]$$

$$=\frac{1}{2}\left(\frac{1}{2}a_0+\sum_{n=1}^{\infty}[a_n\cos(\alpha)-b_n\sin(\alpha)]\right)+\frac{1}{2}\left(\frac{1}{2}a_0+\sum_{n=1}^{\infty}[a_n\cos(\beta)+b_n\sin(\beta)]\right)$$

$$=\frac{1}{2}g(\alpha)+\frac{1}{2}h(\beta)$$

From the foregoing, it can be seen readily that g(α) and h(β) have become two waves, each having half the amplitude of the original wave, the combination of these waves producing a beat which is the input shape f(x).

Thus, using two-channel stereo sound, it is possible to modulate two separate sets of carrier waves so that the replicated EEG waveforms are created as differential beat frequencies between the separate sets. Thus, the method permits the direct application on a frequency base without having to consider the limitation of the spectrum of human hearing. The brain itself synthesizes the signals which cause the effect.

One example may be as follows. If a carrier frequency of 100 Hz were employed in one channel of the audio signal, and a carrier frequency of 104 Hz were employed in the other channel, a binaural beat of 4 Hz would result. In EEG waveform synthesis, as many as 100 separate carrier pairs may be used or a single broad-banded carrier pair may be used to generate a similar number of specific binaural beats that replicate the EEG waveforms in both frequency and amplitude.

A 4 Hz, or a 5 Hz binaural beat would be too low in frequency to hear. Using the Oersted curve mentioned above, the most effective harmonic carrier would be 275 Hz, which is within hearing range. For the multiple waveform situation just discussed, the differential between carrier waves on a single channel also is utilized to produce an FFR.

One type of audio pattern found to be particularly useful in implementing the inventive method is what is known to the inventor as Phased Pink Sound. The full spectrum of audible sound is known commonly as "white" noise. "Pink" sound is known to result from an adjustment in amplitude of white sound to compensate for decline in perception by the human ear at both ends of the audible spectrum.

Phased Pink Sound results from the relative rotational shifting of pink sound from one stereo audio channel to another with cyclic changes in amplitude, frequency, and rate of panning. Such changes generally are synchronous with selected waveforms within the multiple patterns of the binaural beat generating system. Studies have shown that using Phased Pink Sound at a level at least 10 dB lower than the binaural beat signals produces as much as a 30% enhancement in FFR within the EEG waveforms of the listening individual. There is some basis for concluding that Phased Pink Sound provides an audio base that assists the brain in "synthesizing" the binaural beat frequencies normally inaudible in the human hearing process.

Basically, Phased Pink Sound is generated by a digital processor, which converts mathematical sequences, derived from appropriate algorithms, into audible sound. Such digital processors and their operation are well-known in the art, and so are not discussed here. Inherent in such a system is a frequency sensor that synchronizes the phasing with dominant EEG waveforms as those waveforms are introduced from another source.

Examples of suitable algorithms for implementing Phased Pink Sound are as follows:

Looking at some results of the inventive method, FIG. 3A shows the EEG of a subject in a normal waking state. FIG. 3B shows an EEG of the individual after listening to binaural beat sounds produced in accordance with the invention. The Figure shows an FFR response in the 1.5, 4, and 6 Hz signal range.

Likewise, FIG. 3C shows the EEG of a subject in a normal waking state, and FIG. 3D shows an EEG of the individual after listening to other binaural beat sounds produced in accordance with the invention. The Figure shows an FFR response in the 2, 4, and 7 Hz signal range.

FIG. 3E shows the EEG of a subject in a normal waking state, and FIG. 3F shows an EEG of the individual after listening to still other binaural beat sounds produced in accordance with the invention. The Figure shows an FFR response in the 0.5, 3, and 4 Hz signal range.

Finally, FIG. 3G shows the EEG of a subject in a normal waking state, and FIG. 3*h* shows an EEG of the individual after listening to still other binaural beat sounds produced in accordance with the invention. The Figure shows FFR response to 1.5, 2, and 4 Hz signals in amplitude, by frequency.

FIGS. 4A–4C shows a typical contour map of a subject in a normal waking state. It should be noted that the map shows a lack of continuity. Note also the lack of significant amplitude patterns ranging between temporal lobes, and the relative lack of intensity within the frontal area.

In contrast, FIGS. 4D–4F shows a contour map of the same individual after listening to binaural beat sound in accordance with the invention. Note the synchronization between hemispheres, and the high amplitude of activity at the frontal portion of the brain. Note also how the left and right hemisphere brain waves exhibit significantly higher amplitudes in the frequencies found in the original sound stimulus.

The application of the binaural beat signals by headphones or other second producing devices causes the following results:

1. When such audio signals are provided simultaneously with the state of being itself, those specific states can be enhanced. The additional pattern superposed upon the original provides a powerful setting to maintain and/or expand the condition.
2. By recording the audio signals and playing them back, an individual may return to an original or

previously-experienced state of consciousness whenever desired.

3. By listing to recordings of these audio signals, an original pattern or condition induced in one individual may be replicated in other individuals.
4. An individual can be trained, based on sufficient repetition of application of these waveforms, to the point that the individual can recall and replicate these waveforms themselves, without further outside stimulation.

The method of the invention has applications in a number of different areas, not the least of which is the inducement of a state of sleep. Other areas of application include inducement of wakefulness of varying degrees; focusing of attention; inducement of mental and physical relaxation; enhancing intellectual performance in various mental disciplines such as mathematics; enhancement of creativity; the reexperience of previous activity; the acquisition of new abilities which others already have; reinforcement and restoration of weak areas in the mind and body; enhancement and strengthening of mental and/or muscular coordination; and development of integration of entire brain function. Human beings have EEG patterns which are unique to the various states of consciousness and mental and/or physical activity just mentioned, so that the imposition of the appropriate stereo audio signals on the desired EEG wave produces the binaural beat which is necessary to induce the state.

While the invention has been described above in detail with reference to a particular specific embodiment, various modifications within the spirit and scope of the invention will be apparent to those of working skill in this technological field. Thus, the invention should be considered as limited only by the scope of the appended claims.

What is claimed is:

1. A method of inducing states of consciousness in human beings, comprising:
   - providing a replicated electroencephalogram (EEG) waveform indicative of a desired state of consciousness;
   - superimposing said EEG waveform on two separate sets of carrier waves using stereo sound;
   - creating differential beat frequencies between said sets of carrier waves in accordance with said superimposing step; and
   - providing the resulting signals in audio form to respective ears of a human being, to induce said state of consciousness.

2. A method as claimed in claim 1, wherein said creating step includes the step of combining pink with said sets of carrier waves by shifting of said pink sound with respect to said EEG waveform from one stereo audio channel to another, with cyclic changes in amplitude, frequency, and rate of panning.

3. A method as claimed in claim 1, wherein all of said steps are performed repeatedly on a particular individual over a period of time so that the individual is able eventually to reproduce said desired state of consciousness without further audio stimulation.

4. A method as claimed in claim 1, wherein all of said steps are performed using the EEG of one individual, but said applying step is carried out with another individual, so as to transfer the desired state of consciousness of one individual to another.

5. A method as claimed in claim 1, wherein said first providing step comprises the step of providing a plurality of EEG waveforms, indicative of different respective states of consciousness, and each of said superimposing, creating, and second providing steps are performed with each of said plurality of EEG waveforms.

6. A method as claimed in claim 1, wherein said second providing step results in substantial synchronization of major portions of both brain hemispheres of said human being.

[57] **ABSTRACT**

Improved methods and apparatus for entraining human brain patterns, employing frequency following response (FFR) techniques, facilitate attainment of desired states of consciousness. In one embodiment, a plurality of electroencephalogram (EEG) waveforms, characteristic of a given state of consciousness, are combined to yield an EEG waveform to which subjects may be susceptible more readily. In another embodiment, sleep patterns are reproduced based on observed brain patterns during portions of a sleep cycle; entrainment principles are applied to induce sleep. In yet another embodiment, entrainment principles are applied in the work environment, to induce and maintain a desired level of consciousness. A portable device also is described.

METHOD OF AND APPARATUS FOR INDUCING DESIRED STATES OF CONSCIOUSNESS

CROSS-REFERENCE TO RELATED APPLICATION

The present application is related to copending application No. 07/514,460, filed Apr. 16, 1990 now U.S. Pat. No. 5,213,562.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to an improved method of inducing desired states of consciousness, including different levels of sleep, in human beings, using a technique known as frequency following response (FFR), developed by the present inventor. The invention also relates to apparatus for performing the method. A number of areas of applicability of the invention are described, in accordance with different preferred embodiments.

2. Description of the Background Art

In a prior patent, U.S. Pat. No. 3,884,218, the present inventor described a method of inducing different levels of sleep, using the FFR technique, in which brain waves could be made to follow superimposed frequency patterns. These frequency patterns were provided as sine waves, at frequencies known to correspond to different levels of sleep, such as alpha (exhibiting brain wave activity in the range of 8–12 Hz), theta (6–8 Hz), and delta (1–4 Hz). EEGs exhibiting frequencies between 12 and 30 Hz (known as a beta range) are characteristic of awake individuals, though beta activity at even higher frequencies has been observed in different types of mental activities. Gamma activity has been characterized as all activity above 30 Hz; until recently, it has not been possible to monitor brain activity in the gamma range. (It should be noted that the boundaries between gamma and beta, beta and alpha, alpha and theta, and theta and delta are somewhat arbitrary; the foregoing delineations are intended to be exemplary and not limiting.)

The present inventor discovered that the human brain could be entrained to output brain wave patterns these different frequencies. While frequencies corresponding to these different levels of sleep are not audible, by superimposing those frequencies on some type of sound, such as music, it was determined to be possible to induce desired levels of sleep. The individual listening to the music would "hear" the low frequencies, with the desired effect on brain activity.

An improvement on the inventor's patented technique, to induce varied states of alertness, is the subject of copending Application No. 07/514,460, the contents of which are hereby incorporated herein by reference. This copending application describes a general FFR technique using what is known as a binaural beat phenomenon, details of which are provided in that application. Briefly, a binaural beat is produced by sending signals at different frequencies (some Hz apart, depending on the desired effect) to an individual's left and right ears. The difference between the frequencies defines the frequency of the binaural beat. Using this technique, the desired frequency can be introduced into the individual's brain activity, inducing the desired state of consciousness.

The induction of FFR in the human brain in this manner results in the synchronization of activity in the hemispheres of the brain. FIG. 1A shows brain activity without FFR, and FIG. 1B shows brain activity with FFR. The inventor has coined the term HEMI-SYNC (for Hemisphere Synchronization) to describe this phenomenon.

The copending application describes a technique wherein, in one form, sine waves having a frequency corresponding to a consciousness state are superimposed on two different carrier frequencies to form two different signals to set up the binaural beat. In another form, an actual brain pattern, based on an electroencephalogram (EEG) waveform indicative of that consciousness state is superimposed on the different carrier frequencies to form two different signals. In use, each signal is provided to one ear of a subject. The difference in carrier frequencies sets up the binaural beat.

Another, more limited application of the binaural beat phenomenon is found in U.S. Pat. No. 4,834,701. In contrast to the narrow range of frequencies discussed in that patent, in the above-mentioned copending application, the applicability of the binaural beat phenomenon is investigated over a much wider range of frequencies, spanning the spectrum of brain activity.

Through additional investigation involving mapping of brain activities of different individuals, the present inventor has discovered some significance to the fact that, while brain waves at certain frequencies are characteristic of different levels of sleep, brain patterns of different individuals still vary. The inventor has investigated possible enhancements to the FFR effect by making it more generic among individuals, yet still more specific to brain activity than a simple sine wave, or an EEG of a particular individual.

Another area of investigation being performed by the present inventor relates to human sleep patterns. Based on current knowledge of human sleep patterns, it appears that sleep is composed of a series of 90-minute cycles. As stated earlier, the beta stage is one of alertness. The first sleep state is alpha, or mental and physical relaxation. The second is theta, or light sleep. Next is delta, or deep sleep. The inventor has investigated the possibility of providing FFR waveforms in cyclic patterns, replicating these human sleep patterns, to facilitate sleep. Another possibility is to take advantage of the cyclic nature of sleep patterns to provide a more gentle wake-up for a sleeper.

In considering the need for alertness during activities such as work, the inventor also considered how it might be possible to introduce FFR waveforms into ambient noise in one's surroundings to facilitate maintenance of desired states of consciousness. Particularly in environments such as factories, or in offices where office equipment puts out consistent types of noise, it would be desirable to be able to introduce a binaural beat into that noise at different frequencies, to enhance the degree of alertness of factory or office workers as desired.

SUMMARY OF THE INVENTION

In view of the foregoing, according to one aspect of the invention, EEGs for a number of individuals in different states of consciousness are sampled, and EEG waveforms for the group of individuals, corresponding to each identifiable state of consciousness, are combined. A binaural beat then is generated using the combined EEGs.

According to this aspect of the invention, it has been determined that using groups of EEG waveforms from different individuals and combining them to obtain a representative waveform yields a waveform that a person's brain is more likely to replicate than an individual EEG waveform, or a sine wave representation of the EEG waveform. The combination may be simple averaging, though other combination techniques, such as weighted averaging, for combining different numbers of EEG waveforms as desired, are contemplated. Now that the inventor has discovered that combinations of EEG waveforms provide a particularly effective entrainment environment, it will be seen that various ways of combining these waveforms may yield greater or lesser effects.

In accordance with another aspect of the invention, a method for replicating cyclic sleep patterns for a desired sleep period is provided. In a preferred embodiment according to this aspect of the invention, a subject is led from beta, to alpha, to theta, to delta, then back to theta, then alpha, then a rapid-eye movement (REM) or light dreaming sleep, in a sequence of 90-minute cycles, during a sleep period of desired duration. After the expiration of the period, the subject may wake up voluntarily. Alternatively, the invention can provide a gentle external stimulus to lead the subject to a beta state.

With respect to this aspect of the invention, an apparatus is provided which automatically leads an individual through these cyclic sleep patterns, and enables the individual to set a desired sleep period. This device preferably takes advantage of the techniques to be described relative to the first-mentioned aspect of the invention, but is not so limited. The inventive contributions of this second aspect of the invention are considered to lie in the combination of hardware itself which generates the desired sequence of binaural beats, as opposed to the particular software which determines the nature of those binaural beats. In one form, the invention is constituted by an alarm clock which provides a fade-in theta-alpha signal followed by a strong beta-gamma signal shortly before a desired wake-up time.

According to yet another embodiment of the invention, selectable mind-affecting sound patterns are provided to supplement constant ambient noise in any environment. When the noise is not present, the patterns are not provided. The patterns vary in amplitude in accordance with changes in the environmental noise.

In accordance with still another embodiment of the invention, a portable system is provided to enable the wearer to introduce binaural beat signals of frequencies that are selectable in accordance with a desired level of awareness. Depending on the level of sophistication of the device, the binaural beat may be generated using the combined EEG waveforms of the first aspect of the invention, but this last aspect of the invention is not so limited.

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing and other aspects of the invention will be understood by those of working skill in this technological field by reference to the following detailed description of the preferred embodiments of the invention, read in conjunction with the accompanying drawings, wherein:

FIGS. 1A-1C and 1D-1F taken from the above-mentioned copending application, show one example of the results which can be achieved using the inventive techniques;

FIG. 2 is a block diagram of the hardware according to a second embodiment of the invention, and FIGS. 3-5 are more detailed schematics therefor;

FIGS. 6A-6J are drawings, similar to FIGS. 1A and 1B, but showing brain activity during various stages of a sleep cycle, using a technique in accordance with the second embodiment of the invention;

FIG. 7 is a block diagram of hardware in accordance with a third embodiment of the invention;

FIG. 8A is a block diagram of hardware in accordance with a fourth embodiment of the invention, and FIG. 8B a schematic of that hardware; and

FIGS. 9A-9M are graphs of different possible effects of the embodiment of FIGS. 8A and 8B, showing a baseline brain pattern, selected stimulus frequencies and corresponding stimulus waves, and associated response waves.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The method according to a first preferred embodiment of the invention, which has been developed through extensive experimentation, derives from the empirically-observed phenomenon that brain patterns of human subjects are entrained more readily to brain patterns which more closely match their own. In prior implementations of the FFR technique, such as in the inventor's prior patent, in which sine waves having frequencies corresponding to desired levels of sleep were superimposed upon a given frequency, entrainment did occur. Use of the binaural beat phenomenon yielded better results, through synchronization of the hemispheres of the brain.

However, simple repetitive frequencies, or even combinations of such frequencies within different ranges, do not represent brain patterns per se, but rather provide entrainment environments for the brain to follow. It has been determined that, the more closely the entrainment environment parallels normal brain function at different levels of consciousness, the more effective the entrainment effect. This phenomenon is what led to the improvement disclosed in the above-mentioned copending application.

As a further improvement on that technique, as mentioned above, the present inventor investigated the possibility of creating more generic models of brain function at different levels of consciousness. As a result of that investigation, it was determined that combinations of EEG waveforms from different individuals functioning at the same identifiable level of consciousness (e.g. alpha sleep, theta sleep, or delta sleep) provided a superior entrainment environment. In the inventive method according to this aspect of the invention, the brain patterns of 40 to 50 individuals were combined to yield the entrainment environment.

One area of applicability of the techniques of the present invention is in the area of sleep therapy. Many individuals suffer from sleep disorders to varying degrees. It is possible to provide a suitable entrainment environment, based on known sleep cycles prevalent in humans, to help individuals to regulate their sleep patterns, and thus help to solve their sleep disorders. One embodiment of the invention, shown in FIG. 2 and also in FIGS. 3-5, implements the inventive techniques in what the inventor calls a Sleep Processor to aid in the regulation of human sleep cycles.

In FIG. 2, a read-only memory (ROM) 10 stores frequency sequences corresponding to different parts of a human sleep cycle. The stored frequency sequences may be in accordance with a predetermined algorithm, or alternatively may provide a less complex entrainment environment, such as simple averaging. A digital signal processor (DSP) 20 selects different ones of these sequences based on the current time and the time to which an alarm is set. The time is displayed on display 30, and is set using time set 40. The alarm is set to a desired wake-up time using alarm set 50.

During operation, the DSP 20 accesses the ROM 10 and provides an output to a pulse code modulator unit (PCM) 60 accordingly. The PCM 60 provides an output to each of left and right channel speakers 70, 80 which are provided in close proximity to the ears of a human subject. Using headphones enhances the effect.

Some additional detail of operation of the DSP 20 in one aspect of this embodiment now will be provided. A serial port in the DSP 20 generates an interrupt at a 50 KHz rate. An interrupt handler in the DSP 20 computes the various sounds, in one form, by generating sine waves using a pair of integrators:

$$\text{cosine} = \text{cosine} + \text{frequency} \times \text{sine}$$

$$\text{sine} = \text{sine} - \text{frequency} \times \text{cosine}$$

The Sleep Processors needs ten frequencies, five for each channel, and all of these frequencies are generated at the same time. The results are multiplied by ten envelopes, most of which are zero at any moment.

Noise is generated by a well-known 16-bit shift-register algorithm. This algorithm generates a noise signal that repeats every 65535 samples, or about every five seconds. The noise is filtered to sound more like pink or red noise, and less like white noise, and is written into a delay line in RAM. For each channel, the filtered noise is averaged with an earlier sample from the delay line, thus imparting a comb filter response to it.

An additional low-frequency sine/cosine pair is generated, to sweep the comb filter delay. 32-bit arithmetic is used here. The approximate sweep rate is about 1/8 Hz. The low-frequency sine wave is used directly to sweep the delay on one channel. The delay on the other channel is controlled by some mix of the sine and cosine waves. By choosing these and other coefficients properly, any phase and amplitude relationship between the left and right sweep can be obtained. The comb filtered noise for each channel is multiplied by a noise envelope value.

The device is operated as follows. A desired wake-up time is set, much like an alarm clock, and the desired volume is selected. A start/stop button then is pressed to start the cycles for the selected sleep period. Throughout the sleep period, the device repeats a 90 minute cycle of sound that leads the subject through alpha, theta, delta, and back to dreaming sleep. Five minutes before the scheduled wake-up time, a beta signal is introduced to bring the subject back to complete physical wakefulness. When the subject wakes up, he/she hits the start/stop button again to stop the sound sequence.

The sounds produced by the DSP 20 include binaural beat carrier sound patterns utilizing both amplitude and frequency modulation, masking pink sound (a known type of sound described in the copending application), and, optionally, occasional single-word voiced affirmations. The binaural beat audio signals may be in the form of appropriate sine waves, or alternatively may be replicas of actual EEG brain waveforms. In the latter case, either the just-described combined EEG waveforms or a single EEG waveform (as described in the copending application) may be used. The entire pattern of sound and control is generated algorithmically.

One aspect of the effectiveness of the device of FIGS. 2-5 is the spacing of sound carriers at related frequencies so as to engender binaural beat signals not only from channel to channel, but also monaurally, in each audio channel. In this preferred embodiment, three binaural beat frequency signals are created between audio carrier channels, and two amplitude beats per channel also are created, yielding a total of seven beat signals. The inventor has coined the term Septon for this set of beat signals. One example of a septon is as follows:

Left Channel		Right Channel
200 Hz carrier (4 Hz monaural beat)	(4 Hz binaural beat)	204 Hz carrier (4 Hz monaural beat)
204 Hz carrier (4 Hz monaural beat)	(4 Hz binaural beat)	208 Hz carrier (4 Hz monaural beat)
208 Hz carrier	(4 Hz binaural beat)	212 Hz carrier

A standard program according to this preferred embodiment would employ the following sound sequence:

0–5 minutes:

Signal Group A (comprised of replicated EEG waveforms having dominant values in the alpha range)

Signal Group B (15 dB below Group A, generated simultaneously with the sounds of Group A, and comprised of replicated EEG waveforms having dominant values in the theta range)

Phased Pink Sound (six seconds, peak-to-peak, on both left and right channels, 20 dB below Group A)

Voice Inserts (repeated at 40 second intervals, 10 dB below Group A, simultaneously with the other sounds, and comprising short sequences of phrases like "relax" "let go", and "sleep")

5–20 minutes:

Signal Group B

Signal Group C (20 dB below Group B, generated simultaneously with Group B, and comprised of replicated EEG waveforms having dominant values in the delta range)

Phased Pink Sound (15 dB below Group B, having a duration as in the first interval)

Voice Inserts (10 dB below Group B, comprised as above)

20–40 minutes:

Signal Group C

Signal Group D (10 dB below Group C, generated simultaneously with Group C, and comprised of replicated EEG waveforms having dominant values in the lower delta range)

Phased Pink Sound (10 dB below Group C, having a duration as in the first interval)

Voice Inserts (20 dB below Group C, comprised as above) 40–65 minutes:

Signal Group D

Phased Pink Sound (10 dB below Group D, having a duration as in the first interval)

Voice Inserts (20 dB below Group D, comprised as above) 65–80 minutes:

Signal Group C

Signal Group D (10 dB below Group C, generated simultaneously with Group C)

Phased Pink Sound (15 dB below Group C, having a duration as in the first interval)

NO voice inserts
80–90 minutes:
Signal Group B
Signal Group C (10 dB below B, generated simultaneously with Group B)
Phased Pink Sound (15 dB below Group B, having a duration as in the first interval)
NO voice inserts

The foregoing sequence is repeated through the sleep period until the wakeup sequence, approximately five minutes before the set wake-up time:

Signal Group AA (a wakeup sequence, comprising replicated EEG waveforms having dominant values in the beta range, or alternatively a 400 Hz/416 Hz envelope yielding frequencies in the beta range)
Voice inserts (10 dB below Group AA, comprised of short phrases such as "waking up", "refreshed", "bright", and repeated at intervals)

One variation of the foregoing embodiment is an alarm clock which, instead of sounding a loud alarm or other jarring noise at wake-up time, starts a gentle sequence of signals some minutes before, to bring an individual up gently through the various levels of sleep to full wakefulness. A fade-in theta-alpha signal may be provided, followed by a stronger beta-gamma signal.

FIGS. 6A to 6J show the effects of the just-described "sleep processor" embodiment. Column 1 shows distribution of delta frequencies; column 2 shows distribution of theta frequencies; and column 3 shows distribution of alpha frequencies. The top row of graphs is the actual pattern observed in the individual, and the bottom row is the baseline pattern.

FIG. 6A corresponds to a normal waking state. Dominant alpha activity is shown in the occipital area of the brain. In FIG. 6B, pink noise has been applied, without any beat frequencies. A narrower focus of waking state is shown.

In FIG. 6C, a signal sequence corresponding to Signal Group A has been applied. Some gain in theta frequencies are seen, with rapid diffusion of alpha frequencies and movement toward the vertex of the head. In FIG. 6D, a signal sequence corresponding to Signal Group B has been applied. There is further diffusion of alpha frequencies, with some movement of delta and theta activity toward the pre-frontal cortex of the brain.

In FIG. 6E, a signal sequence corresponding to Signal Group C has been applied. There is rapid diffusion of alpha frequencies, and increased power of theta and delta frequencies. In FIG. 6F, a signal sequence corresponding to Signal Group D has been applied. Alpha frequencies are diffused further toward the pre-frontal cortex, and there is a marked increase in theta and delta frequencies.

FIG. 6G, continuing application of Signal Group D frequencies, shows a marked increase in delta activity in the pre-frontal cortex, with a steady decrease in alpha activity at the vertex. In FIG. 6H, another binaural beat stimulation has been applied, and characteristics of stage 3 and 4 sleep may be observed. In FIG. 6I, further evidence of the further binaural beat stimulation is observed. Delta is the dominant frequency here. Alpha and theta activity has moved to the prefrontal cortex. Finally, FIG. 6J shows early awakening activity, with a diffusion of delta activity.

FIG. 7 is a block diagram of hardware in accordance with another embodiment of the invention, having application to the work environment, or anywhere a constant source of noise is present, to allow workers, for example, to maintain a desired state of awareness. The device may contain suitable digital signal processor circuitry, as in the preceding embodiment. One difference is that the operation of the device is keyed to the presence of ambient noise, not to a given time duration or selected sleep period.

The device of FIG. 7 includes a sound generator 200 which, as just mentioned, may comprise a digital signal processor. The generator 200 outputs sound patterns via one or more speakers (left and right channel speakers 210, 220 are shown). A sound level detector 230 detects the level of ambient noise in the room, and provides a signal to the sound generator 200, or activates a cut-off switch (not shown), to discontinue output of the sound generator 200 when the ambient noise level drops below a predetermined level.

The sound level detector also preferably provides a signal to the sound generator 200 to boost the sound pattern output when the ambient noise level increases, so that the effect of the provision of the sound pattern is commensurate with the noise level in the room. Alternatively, the user may simply adjust the volume manually, using one or more knobs (not shown) on the sound generator 200.

A timer 240 may be provided to control the duration of provision of the selected sound pattern, or even to change the sound pattern at different times of day by controlling a selector 250 which the user accesses to select a particular sound pattern to be output. The user may select a given sound pattern in the morning, and the timer 240 may change that pattern automatically, based on a need at different times of day for sound patterns providing different states of alertness.

The sound pattern produced by the device of FIG. 7 varies automatically in amplitude in accordance with changes in the ambient noise, and is discontinued when the noise stops. As a result, the sound remains unobtrusive. Depending on the setting, the produced sound pattern can enhance wakefulness, promote relaxation (as, for example, in rest areas in the workplace), reduce anxiety and stress, or focus attention, among other characteristics.

The basic system of FIG. 7 produces and inserts four different sound patterns which are selected manually so as to merge the output into the constant ambient noise. More sound patterns are possible, depending on the desired overall capabilities of the system. Various modifications are possible. For example, a programmable version may be provided, which changes the form of the sound patterns throughout a work day or night, in accordance with the responses desired.

Selectability of patterns may be accomplished differently in a model intended for use in conjunction with a computer system. The computer operator can input a selection, and may vary that selection as desired throughout the work day.

FIG. 8A is a diagram of a portable embodiment of the invention, for use in providing a desired level of consciousness on an individualized basis. A signal generator 300 preferably includes a digital signal processor 310 and a ROM 320 for storing predetermined signals or sequences of signals which correspond to various desired states of awareness. The signal generator 300 may be a simple tone generator or pair of tone generators which provide outputs to speakers or headphones 330 (such as button-sized headphones) to set up a binaural beat. Output of pink sound or phased pink sound by the generator 300 is desirable to facilitate defocusing of the listener and consequent ability to concentrate on the sounds being produced. A selector **340** enables a user to instruct the signal generator **300** to output signals corresponding to the level of consciousness (e.g. focused concentration, relaxation, alertness) that a user desires.

FIG. **8B** shows a schematic of this embodiment, which the inventor calls a "Mood Minder". This embodiment includes a selector for selecting one of four possible types of signals, corresponding to four respective levels of awareness: awake and alert; concentration; attention; and relaxation. However, the invention is not so limited, as the generator **300** may be capable of producing other possible types of signals. Alternatively, pre-set patterns in the generator **300** may vary when specialized use is required. The key to this embodiment is its portability, enabling the user to carry the device everywhere. The device is battery-operated, and is small enough to fit in an upper coat pocket, for example.

FIGS. **9A–9M** show examples of prestored patterns produced by the generator **300**, and of results achieved in use. FIG. **9A** shows baseline brain waves, with relative power output shown at the right for different frequencies. FIGS. **9B**, **9E**, **9H**, and **9K** show the stimulus frequencies produced for four different respective states of consciousness. FIGS. **9C**, **9F**, **9I**, and **9L** show the stimulus waves corresponding to the superposition of the stimulus frequencies on the baseline wave. FIGS. **9D**, **9G**, **9J**, and **9M** show the results achieved in use. As can be seen, the peak-to-peak amplitudes for the response brain waves correspond closely to those of the stimulus waves.

While the present invention has been described in detail with reference to preferred embodiments, various modifications within the scope and spirit of the invention will be apparent to those of working skill in this technological field. Consequently, the invention should be considered as limited only by the scope of the appended claims.

What is claimed is:

1. A method of inducing desired states of consciousness in human beings, comprising the following steps:
   - combining a plurality of replicated electroencephalogram (EEG) waveforms, each indicative of a particular desired state of consciousness, to produce a combined EEG waveform;
   - superimposing said combined EEG waveform on two separate sets of carrier waves using stereo sound;
   - creating differential beat frequencies between said sets of carrier waves based on said superimposing step; and
   - providing the resulting signals in audio form to respective ears of a human being, to induce said state of consciousness.

2. A method as claimed in claim 1, wherein said combining step comprises mathematically averaging said EEG waveforms to produce said combined EEG waveform.

3. A method as claimed in claim 1, further comprising the step of repeating said combining, superimposing, and creating steps for each of a set of desired states of consciousness, and producing a cycle of sets of resulting audio signals, said providing step comprising providing said cycle of sets of resulting audio signals to respective ears of a human being, to induce each of said desired states of consciousness in cyclic fashion.

4. A method as claimed in claim 3, wherein said cycle corresponds to human sleep patterns, said desired states of consciousness comprising wakefulness, alpha sleep, delta sleep, and theta sleep.

5. A method as claimed in claim 3, wherein said cycle corresponds to human sleep patterns, said desired states of consciousness comprising alpha sleep, delta sleep, and theta sleep, said cycle being approximately 90 minutes long.

6. A method as claimed in claim 5, said method further comprising the steps of providing a plurality of repetitions of said cycle, followed by providing a set of audio signals containing a binaural beat at a frequency indicative of beta consciousness.

7. A method as claimed in claim 1, wherein said creating step includes the step of combining pink sound with said sets of carrier waves by shifting of said pink sound with respect to said combined EEG waveform from one stereo audio channel to another, with cyclic changes in amplitude, frequency, and rate of panning.

8. Apparatus for facilitating sleep in a human subject, comprising:
   - means for setting a wake-up time to select a desired sleep duration;
   - means for generating a first sequence of signals in a cycle corresponding to a human sleep pattern, frequencies of said signals in said first sequence being substantially equal to frequencies of human brain patterns at different levels of sleep;
   - means for repeating said cycle a plurality of times based on the selected wake-up time; and
   - means for waking up said human subject at the selected wake-up time.

9. Apparatus as claimed in claim 8, wherein said means for waking up said human subject comprises means for generating a second sequence of signals a predetermined time before the selected wake-up time, frequencies of said signals in said second sequence being substantially equal to frequencies of human brain patterns at or near an awakened state.

10. Apparatus as claimed in claim 9, wherein said predetermined time is approximately five minutes.

11. Apparatus as claimed in claim 8, wherein said first sequence of frequencies comprises, in order, alpha frequencies, theta frequencies, delta frequencies, and theta frequencies.

12. Apparatus as claimed in claim 8, further comprising means for generating phased pink sound in conjunction with said first sequence of frequencies.

13. Apparatus as claimed in claim 8, wherein said first sequence of signals comprises a plurality of sets of combined brainwaves, each of said sets corresponding to a different level of sleep, said combined brainwaves within a given set being constituted by combined electroencephalogram (EEG) waveforms of a plurality of individuals, taken when said individuals had attained a different respective level of sleep.

14. Apparatus as claimed in claim 13, wherein said EEG waveforms are mathematically averaged.

15. Apparatus for awakening an individual using brain pattern entrainment, said apparatus comprising:
   - means for selecting a wake-up time;
   - means for keeping time; and
   - means, operative a predetermined period before said wake-up time as determined by said means for keeping time, for producing a first sequence of signals having frequencies in the theta-alpha range, followed by a second sequence of signals having frequencies in the beta-gamma range.

16. Apparatus as claimed in claim 15, wherein said means for producing said first and second sequences of signals comprises means for producing said second sequence of signals at a higher amplitude than said first sequence of signals.

17. Apparatus as claimed in claim 15, wherein said first sequence of signals comprises a plurality of sets of combined brainwaves, each of said sets corresponding to a different level of consciousness, said combined brainwaves within a given set being constituted by combined electroencephalogram (EEG) waveforms of a plurality of individuals, taken when said individuals had attained a different respective level of consciousness.

18. Apparatus as claimed in claim 16, wherein said EEG waveforms are mathematically averaged.

19. Apparatus for inducing a desired state of consciousness, said apparatus comprising:

means for detecting presence of a predetermined level of ambient noise;

means, responsive to said detecting means, for generating signals having frequencies substantially equal to frequencies of human brain patterns when said ambient noise is present; and

means for selecting said signals in accordance with desired human activity in said areas.

20. Apparatus as claimed in claim 19, further comprising timer means, connected to said generating means, for generating said signals for a predetermined time set by said timer means.

21. Apparatus as claimed in claim 19, wherein said timer means is connected to said selecting means to enable selection of different ones of said signals in accordance with desired human activity at different times of day.

22. Apparatus as claimed in claim 19, wherein said generating means comprises means, responsive to said detecting means, for increasing an amplitude of said signals in response to an increase in amplitude of said ambient noise, and for decreasing an amplitude of said

signals in response to a decrease in amplitude of said ambient noise.

23. Apparatus as claimed in claim 22, wherein said generating means further comprises means for discontinuing said signals when said ambient noise falls below said predetermined level.

24. Apparatus as claimed in claim 19, wherein said generating means comprises a digital signal processor and a read-only memory (ROM) connected to said digital signal processor, said ROM storing a plurality of sets of signals, each of said sets of signals having frequencies substantially equal to human brain patterns at a desired state of consciousness.

25. Apparatus as claimed in claim 24, wherein each of said sets of signals comprises a plurality of sets of combined brainwaves, each of said sets corresponding to a different level of consciousness, said combined brainwaves within a given set being constituted by combined electroencephalogram (EEG) waveforms of a plurality of individuals, taken when said individuals had attained a different respective state of consciousness.

26. Apparatus as claimed in claim 25, wherein said EEG waveforms are mathematically averaged.

27. Apparatus for awakening an individual using brain pattern entrainment, said apparatus comprising:

means for selecting a wake-up time; and

means, operative a predetermined period before said wake-up time, for producing a first sequence of signals having frequencies in a first predetermined range corresponding to a first state of consciousness, followed by a second sequence of signals having frequencies in a second predetermined range corresponding to a second state of consciousness.

28. Apparatus as claimed in claim 27, wherein said first predetermined range is the theta-alpha range, and said second predetermined range is the beta-gamma range.

MIND CONTROL
TECHNOLOGY
PATENTS
II

Technology To Boggle Your Mind…

Part II in a series of research projects focusing on the official US Patent Office patents detailing technologies for mental monitoring, mind alteration and inducing states of consciousness.

This research project is in progress.
IDN is currently obtaining USPTO documents.
Please find abstract of technologies being researched.

TECHNOLOGY TO BOGGLE YOUR MIND...

This is a listing of various technologies available which can be combined for use in direct or subliminal mind-control systems. Please note that these are mainly private inventions intended for positive uses, but could be applied for negative purposes as well.

- Silent Subliminal Presentation System, US Patent #5,159,703, Oliver Lowery, October 27, 1992. A silent communications system in which non-aural carriers in the very low or very high audio-frequency range, or in the adjacent ultrasonic frequency spectrum, are amplitude-modulated with the desired intelligence and propagated acoustically or vibrationally for inducement into the brain.
- Hearing System, US Patent #4,877,027, Wayne Brunkan, October 31, 1989. A method for directly inducing sound into the head of a person, using microwaves in the range of 100 MHz to 10,000 MHz, modulated with a waveform of frequency-modulated bursts.
- Psycho-Acoustic Projector, US Patent #3,568,347, Andrew Flanders, February 23, 1971. A system for producing aural psychological disturbances and partial deafness in the enemy during combat situations.
- Noise Generator and Transmitter, US Patent #4,034,741, Guy Adams and Jess Carden, Jr, July 12, 1977. An analgesic noise-generator.
- Method and System for Altering Consciousness, US Patent #5,123,899, James Gall, June 23, 1992. A system for altering the states of human consciousness involving the use of simultaneous application of multiple stimuli, preferably sounds, having differing frequencies.
- Subliminal Message Generator, US Patent #5,270,800, Robert Sweet, December 14, 1993. A combined subliminal and supraliminal message generator for use with a television receiver; permits complete control of subliminal messages and their presentation. Also applicable to cable television and computers.
- Superimposing Method and Apparatus Useful for Subliminal Messages, US Patent #5,134,484, Joseph Wilson, July 28, 1992.

US Patent #4,717,343, Alan Densky, January 5, 1988. A method of conditioning a person's unconscious mind in order to effect desired change in the person's behaviour, and which does not require the services of a trained therapist.

- Auditory Subliminal Message System and Method, US Patent #4,395,600, Rene Lundy and David Tyler, July 26, 1983. An amplitude-controlled subliminal message may be mixed with background music.
- Auditory Subliminal Programming System, US Patent #4,777,529, Richard Schultz and Raymond Dolejs, October 11, 1988.
- Apparatus for Inducing Frequency Reduction in Brain Wave, US Patent #4,834,701, Kazumi Masaki, May 30, 1989.
- Ultrasonic Speech Translator and Communication System, US Patent #5,539,705, M. A. Akerman, Curtis Ayers, Howard Haynes, July 23, 1996. A wireless communication system, undetectable by radio-frequency methods, for converting audio signals, including human voice, to electronic signals in the ultrasonic frequency range, transmitting the ultrasonic signal by way of acoustic pressure waves across a carrier medium, including gases, liquids and solids, and reconverting the ultrasonic acoustic pressure waves back to the original audio signal. This invention was made with government support under Contract DE-ACO5-840R21400, awarded by the US Department of Energy to Martin Marietta Energy Systems, Inc.
- Non-Audible Speech Generation Method and Apparatus, US Patent #4,821,326, Norman MacLeod, April 11, 1989.
- Apparatus for Electrophysiological Stimulation, US Patent #4,227,516, Bruce Meland and Bernard Gindes, October 14, 1980.
- Method and Recording for Producing Sounds and Messages to Achieve Alpha and Theta Brainwave States and Positive Emotional States in Humans, US Patent #5,352,181, Mark Davis, October 4, 1994.
- Method and Apparatus for Translating the EEG into Music to Induce and Control Various Psychological and Physiological States and to Control a Musical Instrument, US Patent #4,883,067, Knispel et. al., November 28, 1989.
- Method of and Apparatus for Inducing Desired States of Consciousness, US Patent #5,356,368, Robert Monroe, October 18, 1994. Improved methods and apparatus for entraining human brain patterns, employing frequency-following-response (FFR) techniques and facilitating attainment
- Method of Inducing Mental, Emotional and Physical States of Consciousness, including Specific Mental Activity, in Human Beings, US Patent #5,213,562, Robert Monroe, May 25, 1993.
- Device for the Induction of Specific Brain Wave Patterns, US Patent #4,335,710, John Williamson, June 22, 1982. Brainwave patterns associated with relaxed and meditative states in a subject are gradually induced without deleterious chemical or neurologic side effects.
- Method and Apparatus for Repetitively Producing a Noise-like Audible Signal, US Patent #4,191,175, William Nagle, March 4, 1980.
- Apparatus for the Treatment of Neuropsychic and Somatic Diseases with Heat, Light, Sound and VHF Electromagnetic Radiation, US Patent #3,773,049, L. Y. Rabichev, V. F. Vasiliev, A. S. Putilin, T. G. Ilina, P. V. Raku and L. P. Kernitsky, November 20, 1973. Don't let the nice title fool you. This is the patent for *LIDA*, the infamous Soviet brainwashing machine.
- Non-Invasive Method and Apparatus for Modulating Brain Signals through an External Magnetic or Electric Field to Reduce Pain, US Patent #4,889,526, Elizabeth Rauscher and William Van Bise, December 26, 1989.
- Nervous System Excitation Device, US Patent #3,393,279, Gillis Patrick Flanagan, July 16, 1968. A method of transmitting audio information via a radiofrequency signal modulated with the audio info through electrodes placed on the subject's skin, causing the sensation of hearing the audio information in the brain.
- Method and System for Simplifying Speech Waveforms, US Patent #3,647,970, G. Patrick Flanagan, March 7, 1972. A complex speech waveform is simplified so that it can be transmitted directly through earth or water as a waveform and understood directly or after amplification.
- Means for Aiding Hearing, US Patent #2,995,633, Henry Puharich and Joseph Lawrence, August 8, 1961. Means for converting audible signals to electrical signals and conveying them to viable nerves of the facial system.
- Means for Aiding Hearing by Electrical Stimulation of the Facial Nerve System, US Patent #3,170,993, Henry Puharich, February 23, 1965.
- Hearing Device, US Patent #4,858,612, Philip Stocklin, August 22, 1989. A method and apparatus for simulation of hearing in mammals by introduction of a plurality of microwaves into the regions of

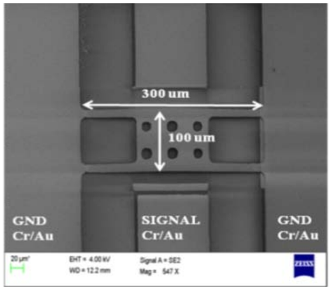
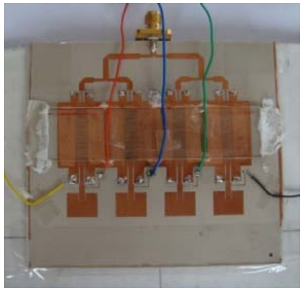
ECE: Microwave Engineering

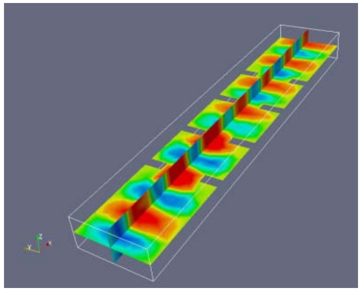
K.J. Vinoy

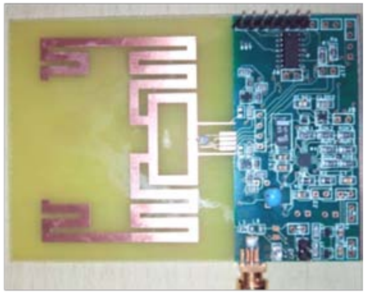
- Low-Actuation Voltage Capacitive RF MEMS Switch (<10V)
  - Low-complexity fabrication process to enhance process yield
  - High reliability: no failure even up to 10 million cycles of operation tested
- Meso-scale Electrostatic Phase Shifter on microwave Laminate (MEPL)
  - Utilizes modern printed circuit board fabrication technology.
  - X-band monolithic antenna array system on the microwave laminate board demonstrated.

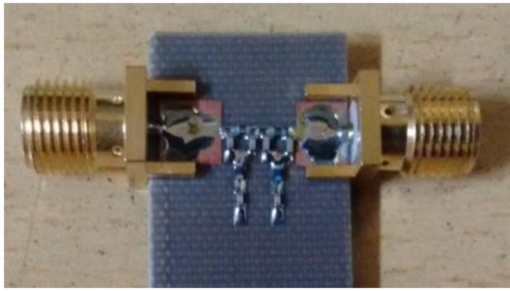
- Wideband group delay engineering in RF circuits for radar, medical imaging, and spectrum sensing.
  - Demonstration uses two stage All – Pass Networks; can be extended over multiple stages to obtain a higher bandwidth and/or higher group delay slope.
- RF energy harvesting circuits
  - Integrated with RF transmitters and sensors for practical IoT nodes
  - High efficiency RF-DC converter which can operate at input power of -20dBm (10µW) at 2.4GHz using UMC 130nm process MOSFETs.
- FEM based algorithms for Electromagnetic circuits & components (periodic structures such as metamaterials)
  - Fast computation of electromagnetic propagation characteristics
  - Especially suited for evaluation of processes uncertainties









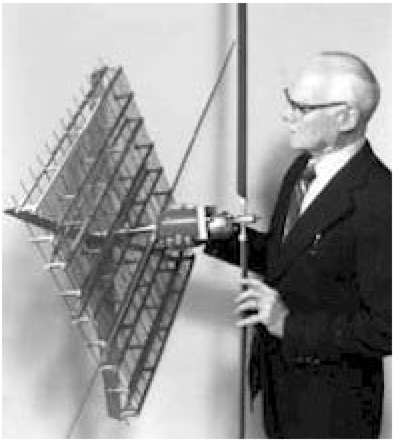


Setting the stage….

- **Introduction**
  - **Wireless Power Transfer**
    - **Energy Harvesting**
  - **Internet of Things**
- Highlights of Recent Development (Hardware)
  - Powering wireless terminals
  - RFID with integrated sensors

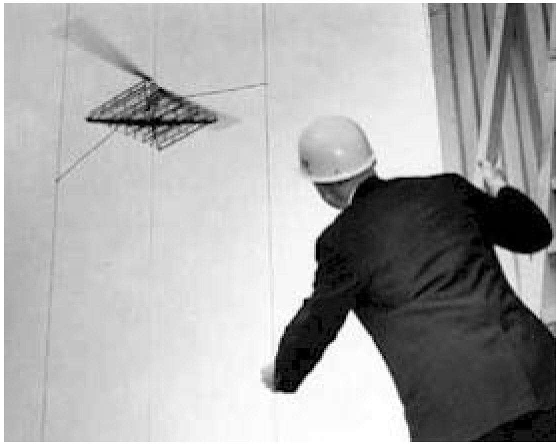
Ongoing Research Challenges

Wireless Power Transfer (WPT)



- Indicates transfer of electric energy remotely

- WPT has a long history!!
  - Tesla demonstrated it in 1899 by wirelessly powering fluorescent lamps 40 kms away from the power source.
  - Had multiple patents in early 1900s.



- In 1960s W.C. Brown coined the term Rectenna, which he used to directly converts incoming microwaves to DC.
  - He demonstrated its ability to power a helicopter solely through microwaves for 10 hours continuously.

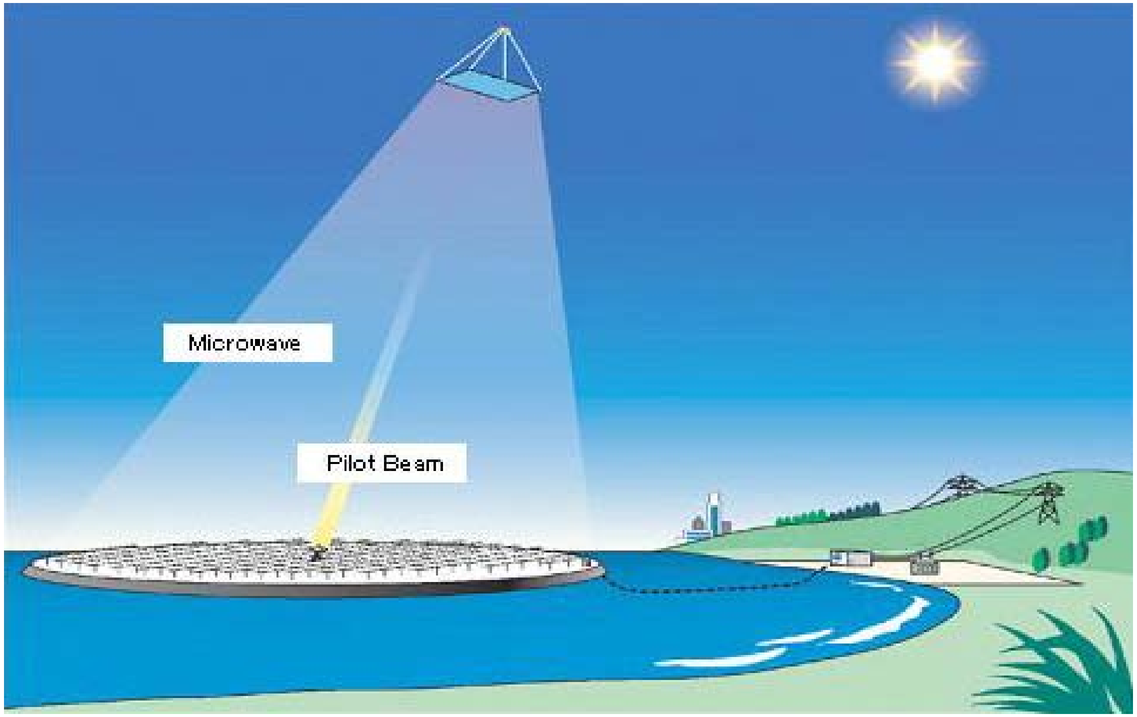
- These demonstrations involved dedicated sources with **large power to transmit over long distances**.

http://mainland.cctt.org/istf2008/brown.asp

SSPS

- Space Solar Power Satellites

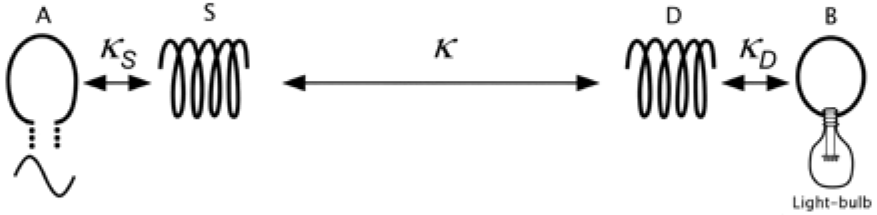
- WPT is widely investigated for putting **solar power generating satellites** into space and transmitting power to Earth stations. (Mainly in Japan)

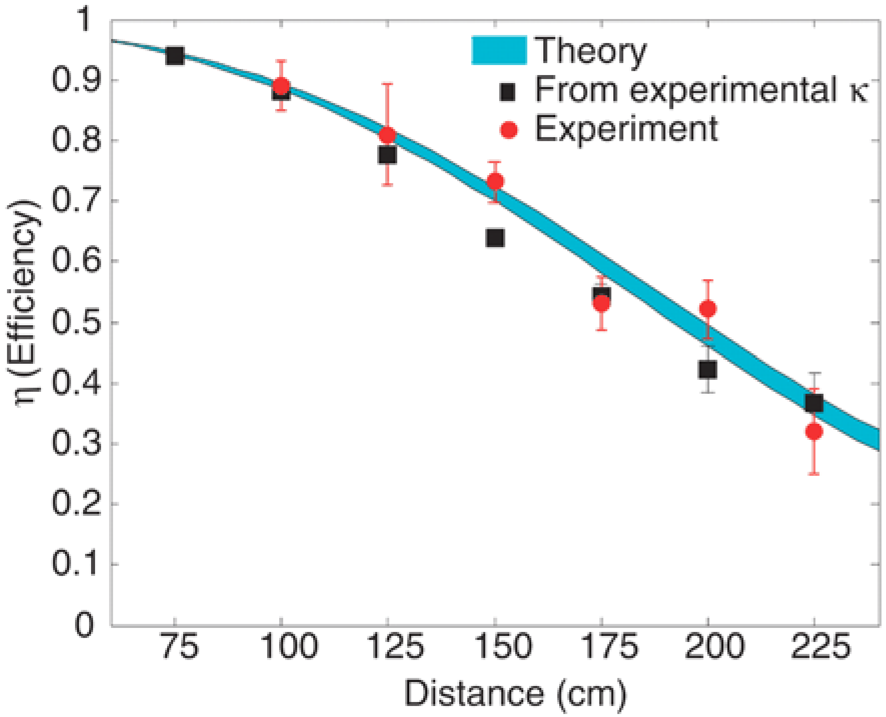


http://www.jspacesystems.or.jp/en_project_ssps/

Near field Wireless Power Transfer

- Recent demonstration by MIT to transfer high RF power (Watts) transferred across meters.
- Resonant coils are used
- Typically at 100 kHz to 10's of MHz
- Many new applications emerged





André Kurs et al, Wireless Power Transfer via Strongly Coupled Magnetic Resonances , Science, Vol. 317 no. 5834 pp. 83-86. 6 July 2007.

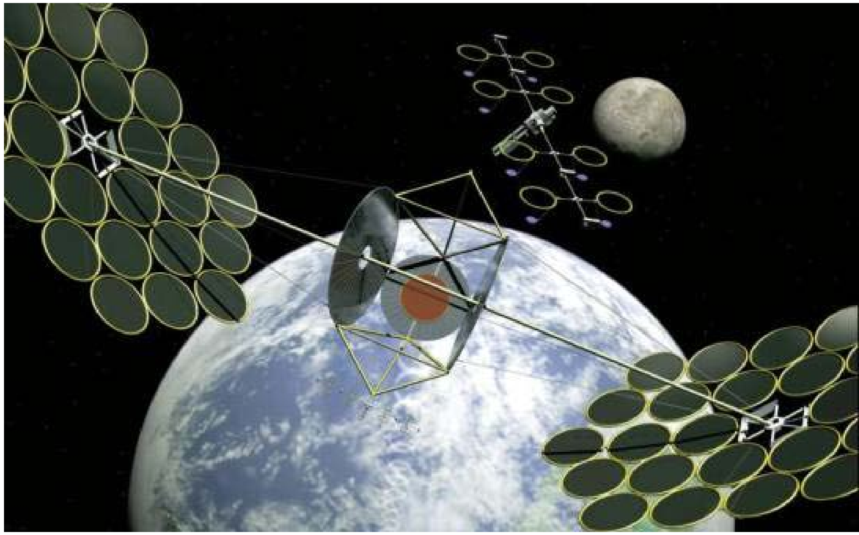
Far → Near in WPT

- Free space loss factor is a major bottleneck for power transfer at large distances

- Short distance/ Near field options
  - MIT demonstration (2007)
  - Qi Standard
  - Phone charging solutions
  - Vehicles running on wireless power

- Two extremes in WPT
  - mW ← → MW
  - mm ← → 1000s km
  - 100kHz ← → 2.4/5.8GHz
  - 10cm x 10cm ← → km x km
  - Commercial vs bluesky



Far Field Transfer of RF Energy

- Focus of this talk
- Applications: RFID tags, Wireless Sensor Network nodes, biomedical equipment, home automation and structural monitoring can benefit from RF energy harvesting.
- Block diagram and a design example:

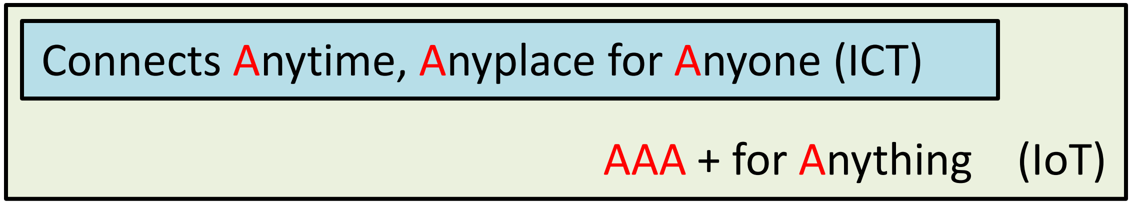
A New Paradigm: Internet of Things (IoT)

- IoT refers to uniquely identifiable objects and their virtual representations in an Internet-like structure.



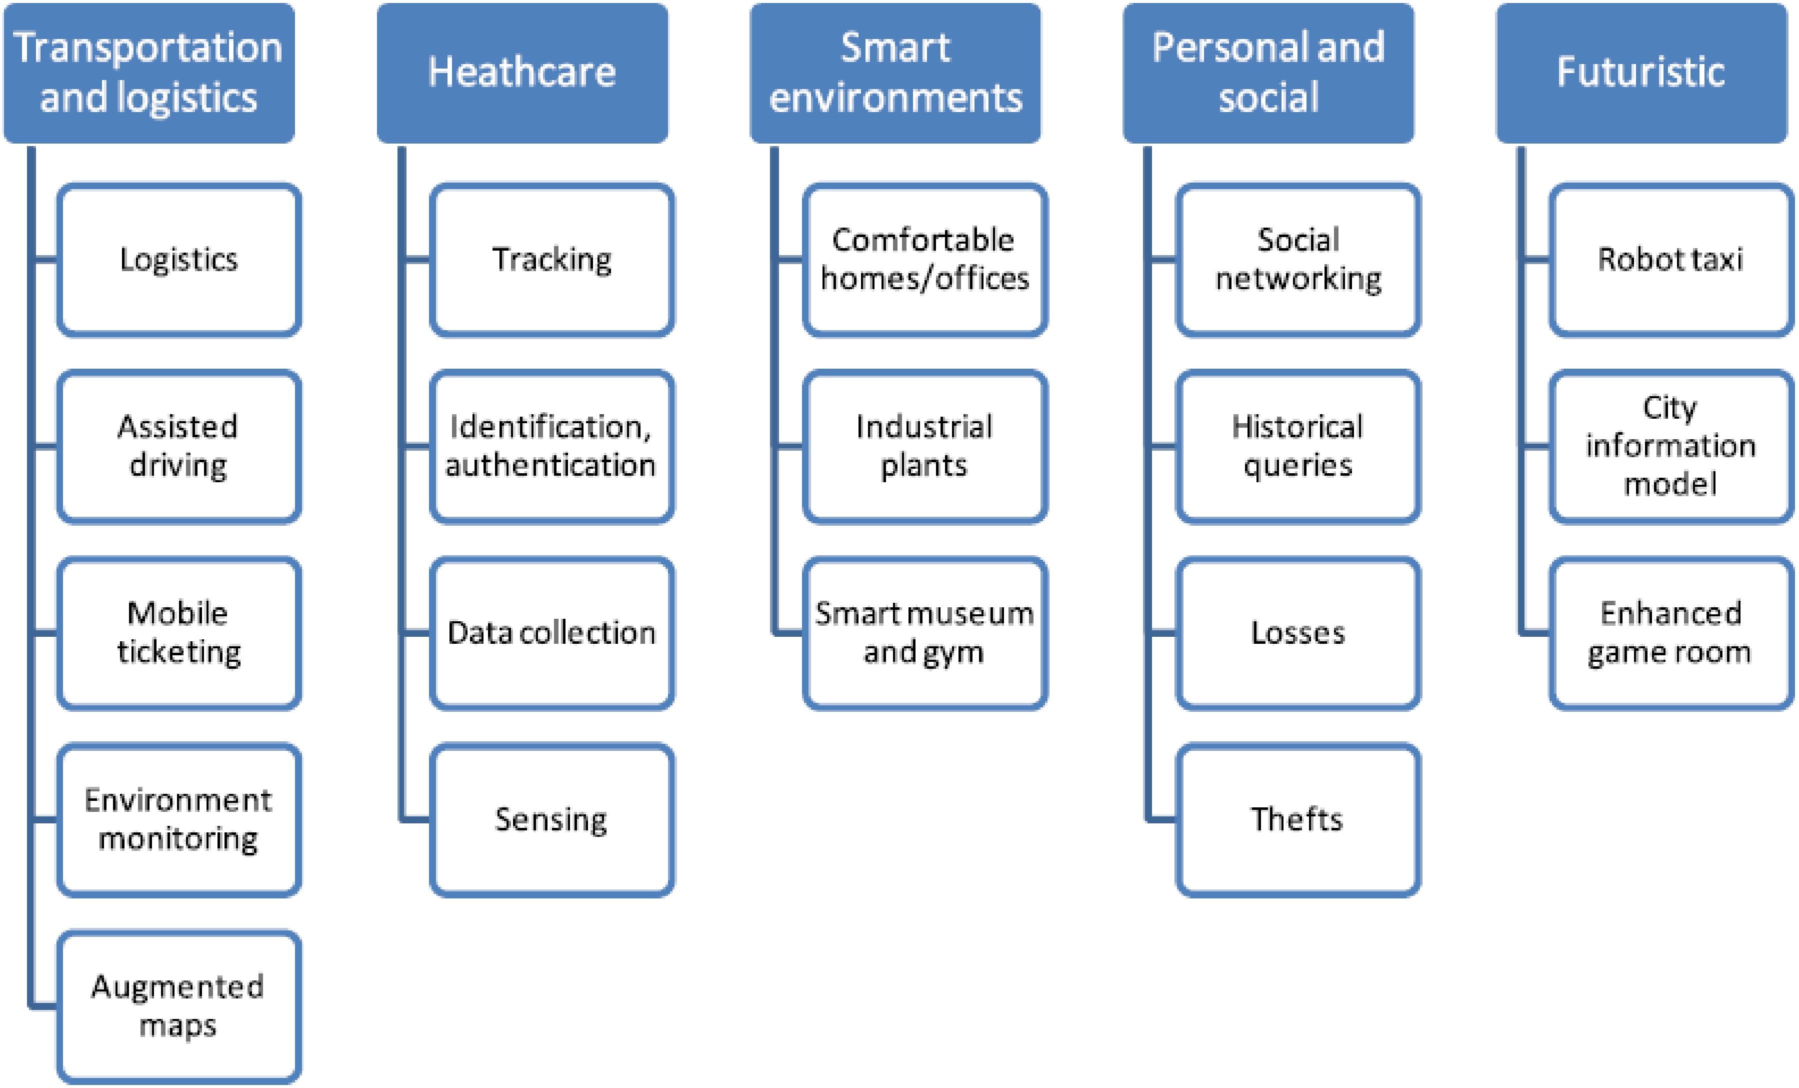
Connects Anytime, Anyplace for Anyone (ICT)

AAA + for Anything (IoT)

- IoT is a scheme for connecting things: sensors, actuators, and other smart technologies, thus enabling person-to-object and object-to-object communications.

- **Continuous availability of power is crucial for their deployment**

IoT Applications



- Transportation and logistics
  - Logistics
  - Assisted driving
  - Mobile ticketing
  - Environment monitoring
  - Augmented maps
- Heathcare
  - Tracking
  - Identification, authentication
  - Data collection
  - Sensing
- Smart environments
  - Comfortable homes/offices
  - Industrial plants
  - Smart museum and gym
- Personal and social
  - Social networking
  - Historical queries
  - Losses
  - Thefts
- Futuristic
  - Robot taxi
  - City information model
  - Enhanced game room

L. Atzori , A. Iera, G. Morabito, The Internet of Things: A survey Computer Networks 54 (2010) 2787–2805

Comparison of different wireless protocols

Today, a lot can be done at low power!!

Characteristics of key 2.4GHz ISM Band Radios studied :

	BLE	ANT	Zigbee	WLAN
Topologies	P2P , Star	P2P , Star, tree, mesh	P2P , Star, mesh	P2P , Star
Modulation	GFSK	GFSK	OQPSK	DSSS (802.11b)
Max data rate	1Mbps	12.8-60 Kbps	250Kbs (@2.4Ghz)	1- 11Mbps (802.11b)
Throughput	305 kbps	20Kbps	100Kbps	6Mbps (802.11b)
Range (in m)	10-100(0-10dBm)	30 (@ 0dBm)	10-100 (0-20dBm)	100+(20dBm)
Max nodes in piconet	7	65533	Star-65536	32-64
Battery life	1-2 years (coin cell)	1-2years (coin cell)	100-1000 days	0.5-5days

Key Aspects :

BLE is robust and has lowest power consumption but cannot natively form mesh networks,

Zigbee can support large mesh networks, power consumption is higher than BLE and throughput is lower: It is suitable for low data rate, low power, large size networks.

WLAN is primarily suitable for transferring bulk data at high speeds, Not suitable for low power applications.

Power Requirements in Common WSN

	Crossbow MICAz	Intel IMote2	Jennic JN5139
Radio standard	IEEE802.15.4/ZigBee	IEEE802.15.4	IEEE802.15.4/ZigBee
Typical range	100m (outdoor), 30m (indoor)	30m	1 km
Data rate (kbps)	250 kbps	250 kbps	250 kbps
Sleep mode (deep sleep)	15 μA	390 μA	2.8 μA (1.6μA)
Processor only	8mA active mode	31–53mA$*$	2.7+0.325mA/MHz
RX	19.7mA	44mA	34mA
TX	17.4mA (+0dbm)	44mA	34mA (+3 dBm)
Supply voltage (minimum)	2.7V	3.2V	2.7V
Average	2.8mW	12mW	3mW

JM. Gilbert$*$ F. Balouchi, Comparison of Energy Harvesting Systems for Wireless Sensor Networks, International Journal of Automation and Computing 05(4), October 2008, 334-347

	Jennic JN5148	**TI- CC430**	**BLE**	**Zarlink ZL70250**
Active mode current at 16MHz [mA]	6	4	6.7	3.2
Deep sleep current [nA]	100	1000	400	20
Transmission current [mA]@Tx-power [dBm]	15@2.5	18@0	36@2	2@-10
Transmit frequency	2.4 GHz	2.4 GHz	2.4 GHz	868 MHz
Wakeup time [ms]	1	3	0.12	0.16
Energy consumption for a transmission cycle of 2ms [µJ]	183	300	196	32
Power supply voltage [V]	2.2 – 3.6	1.8 -3.6	2-3.6	1.2 – 1.8

In perspective

- Energy requirements in different devices/systems
- 6 orders of magnitude variation!!!
- Energy requirements in WSN
  - Depends on the complexity/ standard/ range
  - eg 90 μW to power a pulse oxymeter sensor, to process data and to transmit them at intervals of 15 s

Device type	**Power consumption**
Smartphone	1W
MP3 decoder chip	58 mW
Hearing aid	1 mW
Wireless sensor node	100 μW*
RF receiver chip	24 mW
GPS receiver chip	15 mW
6D motion sensor	14.4 mW
Cell phone (standby)	8.1 mW
PPG sensor	1.473 mW
Humidity	1 mW
Pressure	0.5 mW
3D accelerometer	0.324 mW
Temperature	27 μW
Cardiac pacemaker	50 μW
Wristwatch	7 μW
Memory R/W	2.17 μW
A-D conversion	1 μW

J Yun, S. Patel, M.Reynolds, G. Abowd “A Quantitative Investigation of Inertial Power Harvesting for Human-powered Devices,” UbiComp’08, September 21-24, 2008, Seoul, Korea.

R.J.M. Vullers, et.al, Micropower energy harvesting, Solid-State Electronics 53 (2009) 684–693

Power Density from Various Harvesters

Ambient RF	< 1 μW/cm^2
Ambient light	100 mW/cm^2 (directed toward bright sun)
	100 μW/cm^2 (illuminated office)
Thermoelectric	60 μW/cm^2
Vibrational	4 μW/cm^3 (human motion ~Hz)
microgenerators	800 μW/cm^3 (machines ~kHz)
Ambient airflow	1 mW/cm^2
Push buttons	50 μJ/N
Hand generators	30 W/kg
Heel strike	Up tp 7 W for 1 cm deflection

Power requirements in conventional sensor network nodes may not be met by harvesting alone!

J Yun, S. Patel, M.Reynolds, G. Abowd "A Quantitative Investigation of Inertial Power Harvesting for Human-powered Devices," UbiComp'08, September 21-24, 2008, Seoul, Korea.

Electromagnetic: Solar → RF

- PV is a good source of energy. Recall,

Ambient light	100 mW/cm^2 (directed toward bright sun)
	100 µW/cm^2 (illuminated office)

- However, it light is not always available.
  - At night
  - Specific scenarios: in a closed chamber, or mine.

- RF is an alternative
  - Unlike others, RF sources may be ambient or intentional.
  - Ambient sources such as base stations or broadcast stations
  - Special sources: RF ID reader, Phone charger, special beacons

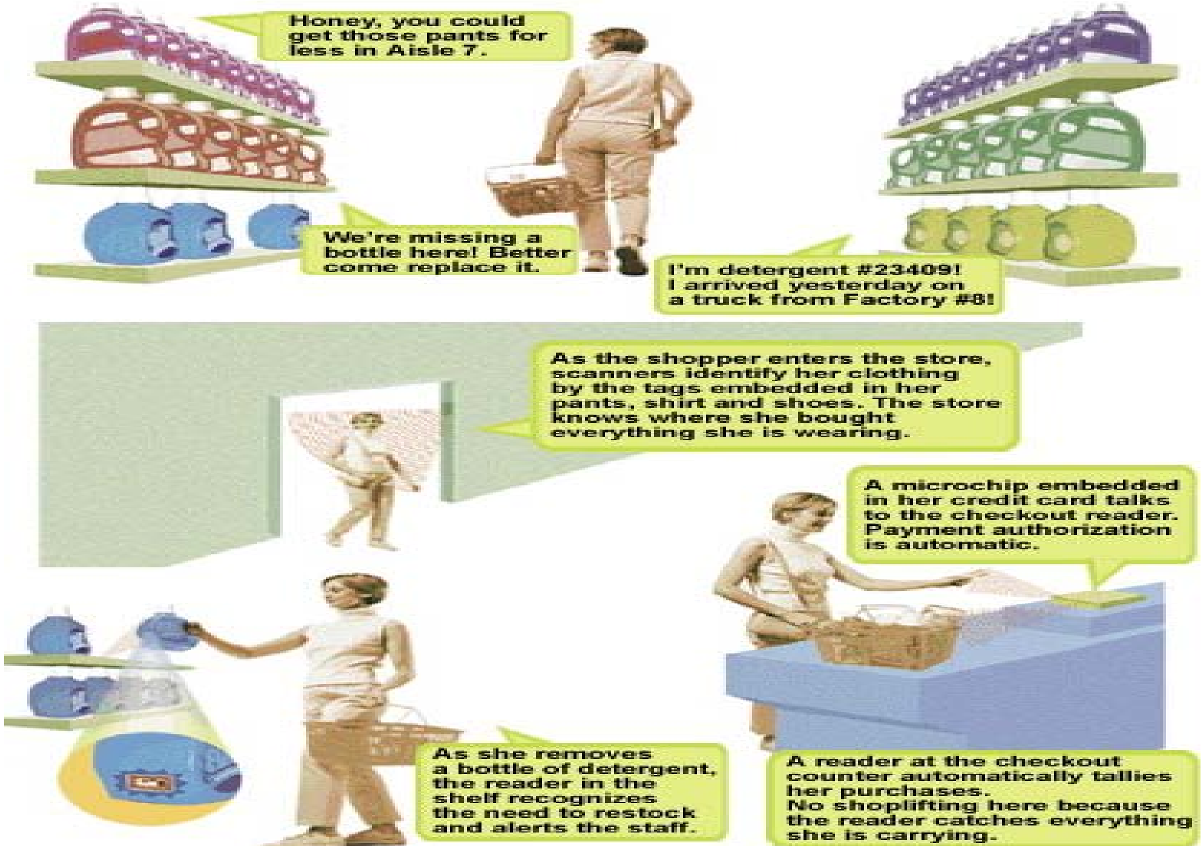
Demand and Supply

- The peak currents needed during transmit and receive operation is not achievable using the harvester alone.
- Buffering is also needed to ensure continuous operation during times without power generation.
- The combination of an energy harvester with a small-sized storage is the best approach to enable energy autonomy of the network over the entire lifetime.
  - Rechargeable battery
  - Thin film batteries
    - can be integrated directly in Integrated Circuit (IC) packages in any shape or size,
    - Flexible when fabricated on thin plastics
    - Thin film batteries have high impedance;
    - Low discharge efficiency compared to Li-ion batteries
  - super capacitor
    - Leakage in super capcitors depends on the voltage. Low at low voltage

Internet of Things (IoT)

Embedding short-range mobile transceivers into a wide array of gadgets and everyday items, enabling new forms of communication between people and things, and between things themselves.

RFID + **Sensor** + **Smart Tech** + **Nano Tech** = IoT



Honey, you could get those pants for less in Aisle 7.
We're missing a bottle here! Better come replace it.
I'm detergent #23409! I arrived yesterday on a truck from Factory #8!
As the shopper enters the store, scanners identify her clothing by the tags embedded in her pants, shirt and shoes. The store knows where she bought everything she is wearing.
A microchip embedded in her credit card talks to the checkout reader. Payment authorization is automatic.
As she removes a bottle of detergent, the reader in the shelf recognizes the need to restock and alerts the staff.
A reader at the checkout counter automatically tallies her purchases. No shoplifting here because the reader catches everything she is carrying.

When shopping in the market, the goods will introduce themselves.

When entering the doors, scanners will identify the tags on clothing.

When paying for the goods, the microchip of the credit card will communicate with checkout reader.

When moving the goods, the reader will tell the staff to put a new one.

Introduction to RFID

- The reader converts incident field and returns useful data
- In passive RFID systems reader transmits EM energy that "wakes up“ the tag and provides power for the tag to respond to the reader.

integrated circuit

Backscatter Communication

- **Backscatter** is the reflection of signals back towards their source.
  - In this scheme, two devices communicate using incident (or ambient) RF as the source of power.
  - Backscattering is achieved by changing the impedance of a receiver in the presence of an incident signal.
  - When waves encounter a new media that have different impedances, a part of the wave is reflected.
  - The reflection depends on the difference in the impedances.
- By modulating the impedance at the receiver port, one can control the scattered RF energy, hence enabling information transmission.

abc.cs.washington.edu/files/comm153-liu.pdf

RFID → IoT

- RFID
  - Uses radio waves for identifying or tracking the object.
  - Proven to be a simple and cost effective system
  - Tags are very cheap and is possible to be attached to everyday objects.

- RFID is considered a prerequisite of **Internet of Things.**

- **Example: RFID tags can be integrated with sensors**
  - When a reader reads a tag, the sensor information will be sent to the reader along with the identity of the object.

WISP

- Wireless Identification Sensor Platform (2009)
  - WISPs are a wireless, battery-free sensing and computation platform, powered by harvested energy from off-the-shelf UHF RFID readers.
  - To a RFID reader, a WISP is a EPC gen1 or gen2 tag; but inside the WISP, the harvested energy is operating a 16-bit general purpose microcontroller.
  - The microcontroller can perform computing tasks, including sampling sensors, and communicate to the RFID reader.
  - WISPs have been built with various sensors, WISPs can write to flash and perform cryptographic computations.

A collaboration between Intel Research Seattle and the University of Washington.

WISP 4.1DL
Intel Research Seattle

http://wisp.wikispaces.com/Wisp+4.1+DL

RFID Sensors (Products)

- ID operation is passive; yet most sensors require power sources

- Powercast has a wireless sensor that is battery-less. Uses RF energy harvesting.
- Harvesting schemes works at power as low as -12dBm. (RF-DC conversion efficiency above 40% only above -8dBm)
- Harvested power >0.4mW for RF in of >-1dBm.
- Multiple custom ICs and discretes

- Other suppliers include
  - Phase IV
  - RFID sensor systems
  - etc

Battery-less Wireless Terminals

- Most of our work in this direction was towards battery-less terminals
- Long life terminals without wiring
- These are useful when
  - Terminals are embedded within structures (or body)
  - Devices to be deployed in hostile environments
  - Use of battery is not allowed (potential cause for explosion)
- Other factors
  - Cost, weight, etc.
- Primary focus: use of radio frequencies (ambient/intentional)

Ambient RF Sources

- Several sources:
  - WiFi Access points (mW) [2.4/.6GHz]
  - Cellular Tower (W) [900/1800 MHz]
  - TV Broadcast (MW) [150-450MHz]
  - FM broadcast (kW) [90-108MHz]
  - AM Radio broadcast (kW) [<1MHz]

- In general
  - Lower frequencies help non-line-of sight propagation
  - Power availability from ambient sources is limited and varies from place to place.

- Note
  - Unlike other sources, most practical RF harvesters (eg in RF ID) depend on **intentionally generated energy**.
  - This is called **wireless power transfer (WPT)** in the conventional RF/Microwave parlance.

Wireless Communication System

- Power transfer scheme is no different!!

Antenna Fundamentals: Directivity

This is the ratio of the radiation intensity in a given direction to the radiation intensity averaged over all direction

Average radiation intensity, $U_0 = \dfrac{P_{rad}}{4\pi}$

Directivity,

$$D(\theta,\phi) = \frac{U(\theta,\phi)}{U_0} = \frac{4\pi U(\theta,\phi)}{P_{rad}}$$

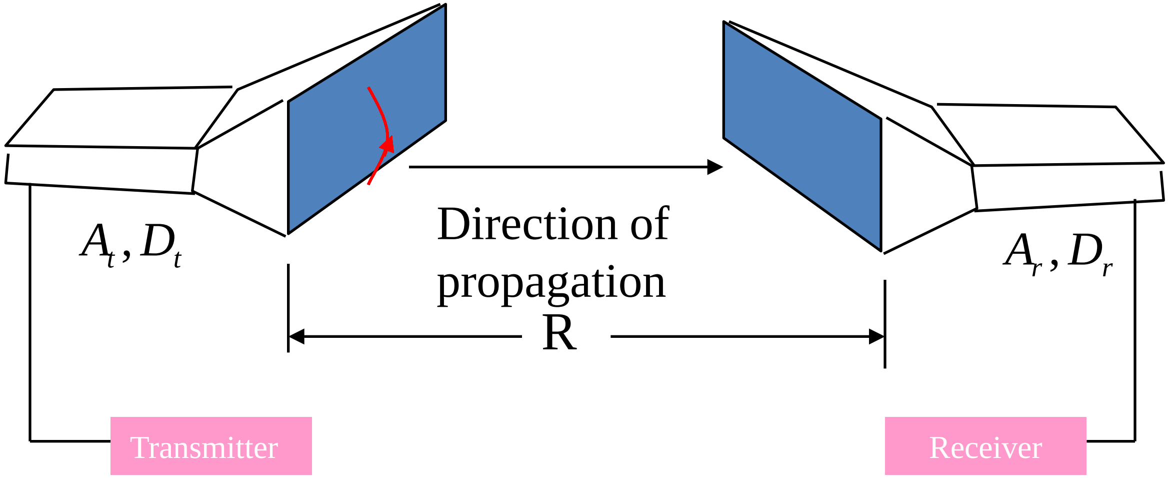
- If direction is not specified, it implies the direction of maximum radiation intensity

$$D_{\max} = \frac{4\pi U_{\max}}{P_{rad}} \qquad D_{dB} = 10\log D$$

Maximum directivity and Maximum effective area

The radiated power density by a transmitter at a distance R

$$W_t = \frac{P_t D_t}{4\pi R^2}$$



A_t, D_t
Direction of propagation
R
A_r, D_r
Transmitter
Receiver

Power received

$$P_r = W_t . A_r = \frac{P_t D_t A_r}{4\pi R^2}$$

$$or, \; D_t . A_r = \frac{P_r}{P_t} . 4\pi R^2$$

By reversing the transmission direction

$$D_r A_t = \frac{P_r}{P_t} \cdot 4\pi R^2$$

$$\therefore \frac{D_t}{A_t} = \frac{D_r}{A_r}$$

this can be generalized by

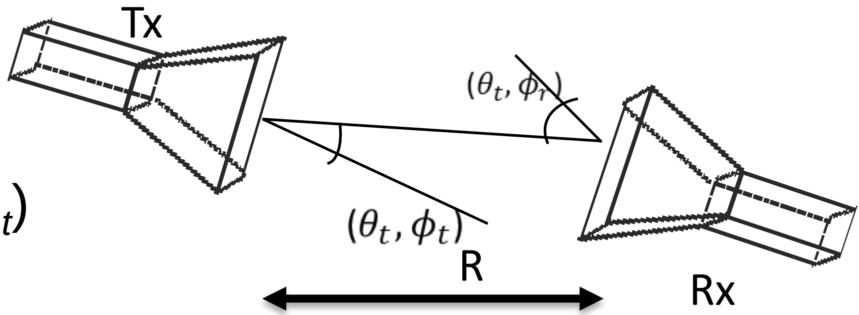
$$\frac{D_1}{A_1} = \frac{D_2}{A_2} = k = \frac{4\pi}{\lambda^2}$$

$if, \; D_0 = \text{max. directivity}$

$A_{em} = \text{max. effective area}$

$$D = \frac{4\pi A_{em}}{\lambda^2}$$

Frii's Transmission Equation



- The radiation intensity for an isotropic radiator is $W_0 = \frac{P_t}{4\pi R^2}$
- For an antenna of gain G_t (or directivity D_t)

$$W_t = \frac{P_t G_t(\theta_t,\phi_t)}{4\pi R^2} = e_t \frac{P_t D_t(\theta_t,\phi_t)}{4\pi R^2}$$

- The effective aperture of a receiving antenna is given by $A_r = e_r D_r(\theta_r,\phi_r)\frac{\lambda^2}{4\pi}$
- Therefore,

$$P_r = e_r D_r(\theta_r,\phi_r)\frac{\lambda^2}{4\pi} W_t = e_t\, e_r D_t(\theta_t,\phi_t) D_r(\theta_r,\phi_r)\frac{\lambda^2}{(4\pi R)^2}|\hat{\boldsymbol{\rho}}_t\cdot\hat{\boldsymbol{\rho}}_r|^2$$

$$\frac{P_r}{P_t} = e_t e_r D_t(\theta_t,\phi_t) D_r(\theta_r,\phi_r)\frac{\lambda^2}{(4\pi R)^2}|\hat{\boldsymbol{\rho}}_t\cdot\hat{\boldsymbol{\rho}}_r|^2$$

$$\frac{P_r}{P_t} = e_{cdt} e_{cdr}(1-|\Gamma_t|^2)(1-|\Gamma_r|^2) D_t(\theta_t,\phi_t) D_r(\theta_r,\phi_r)\frac{\lambda^2}{(4\pi R)^2}|\hat{\boldsymbol{\rho}}_t\cdot\hat{\boldsymbol{\rho}}_r|^2$$

- When the antennas are pointing towards each others' peak radiation direction,

$$\frac{P_r}{P_t} = G_{0t} G_{0r}\left(\frac{\lambda}{4\pi R}\right)^2$$

Note that includes a loss factor (usually called **Free space Loss factor)**
Does not include dissipation/attenuation in medium; caused by spreading

Some numbers on Radiative form of WPT…

- Practical systems will have
  - Operational frequencies in ISM bands.
  - Most terminals are compact.
  - Antenna efficiency is compromised.
  - Nearly isotropic radiations expected.

- Main bottleneck is the physical limits in transmission.

$$P_r = P_t{*}G_t{*}G_r{*}(\lambda/4\pi r)^2$$

  - At 1 GHz (λ=30cm) r=1m; Antenna gain @0dBm, free space loss factor is about **0.06%**
  - Even with a moderate gain transmitter antenna (6dBi) power received @1m for 1W transmission, is just 2mW.
    - Drops to 23μW at 10m !!
    - **The voltage of the signal is low!!**

- In radiative power transfer, Distance from transmitter is a major concern.

Some questions addressed in our work

- **Harvesting of ambient radiations or Radiative transfer of energy addressed**
  - Is it possible to harvest the RF energy from base stations
  - Are there other viable sources of RF energy

- Can low power communication systems be designed to operate entirely from harvested energy
  - Integrate sensors, control, etc

- Can we use RF EH/ WPT to increase the range of backscatter communication (RFID scenario)

Design of Rectifiers

Required for converting incoming RF into DC power.

The challenge lies in maximizing the power conversion efficiency for low input power and minimizing the dimensions.

- RF to DC conversion by rectification of the incident RF signal by a ***Schottky diode***
  - Most diodes have a finite cut-in voltage
  - Diode is a non-linear device (performance depends on current or load)
  - Impedance matching required between antenna and diode
  - In most cases, the input voltage needs to be boosted

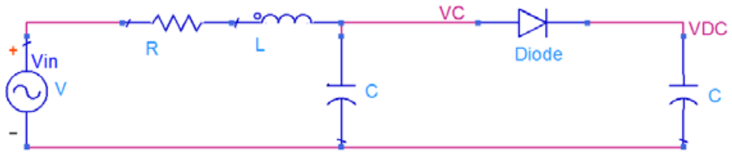
Voltage magnification in Matching circuit

- Matching circuit is required to provide impedance match between antennas (50Ω typical) to diode terminated with high impedance load (capacitor and/or high R in parallel).
  - LC matching networks provide voltage magnification.
  - This helps the diode conduct a good fraction of half cycle.
- The higher the voltage across the diodes, the more efficient the rectifier gets.
  - In practice Q is limited
  - Applications requiring higher voltages, a voltage multiplier configuration is used.



$$V_C = V_{in} \times \frac{\frac{1}{j\omega C}}{R + j\omega L + \frac{1}{j\omega C}}$$

At resonance,

$$V_C = V_{in} \times \frac{1}{j\omega_0 CR} = -jQV_{in}$$

Other Possibilities using Wireless Power Transfer

- Power transfer by radiation is not efficient
- Waveguiding systems can ensure better transmission of power
  - Loss in waveguide is a small fraction of a dB/m (~0.2dB/m)
  - Metal ducts may carry higher order modes with higher losses
  - Extended to conducting ducts, Tunnels, mine shafts etc with some compromise
- Other possibilities
  - Surface wave
  - Focusing of fields

- Empty enclosures with metallic walls
  - Containers, tanks, airplane cabin, trains, etc
  - Other objects in the path may reduce the efficiency!

3: Antenna for RFID sensors

- Work involved design of antenna for RF harvesting sensors
  - These fuel level sensors to be deployed in a fuel tank of aircrft.
  - Optimization of design should focus on efficiency
  - High gain or directivity is not required.

- EH platform to be used with RFID sensors deployed inside fuel tank

- Requirements/Assumptions:
  - Incident energy is of random polarity and direction.
  - Operating frequency is 902MHz-928MHz.
  - Antenna must operate in air (relative permittivity = 1) and fluid (relative permittivity = 2.1)
  - Dimensions of planar antenna board:
    - Target dimensions: 3 in. x 2 in.
    - Maximum dimensions: 6 in. x 4 in.

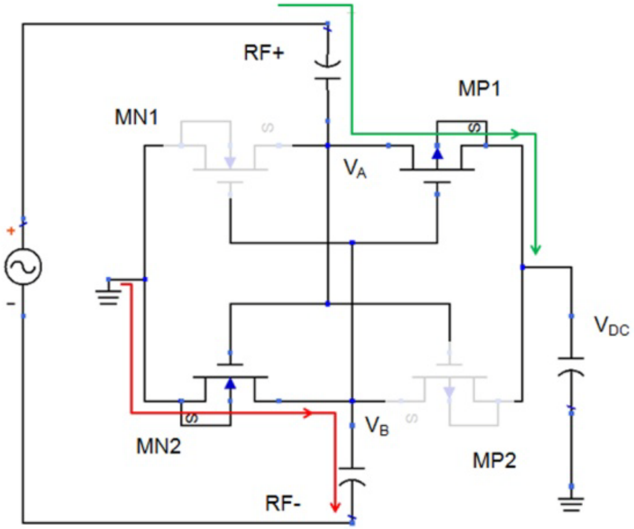
Cross-coupled Rectifiers for Low Power

- CMoS integration requires diodes using MoSFETs.
- Simple diode connected configurations are not effective at low power/voltage levels
- In Cross Coupled Rectifiers
  - Biasing of MOSFETs by charge stored in capacitors. This is a way of threshold compensation.
  - Low ON resistance due to high overdrive voltage.
  - In both cycles of input, output capacitor is charged. Although DCP uses both cycles, only alternate cycles charges the output capacitor and the other cycle charges the input capacitor.



DC-DC converter

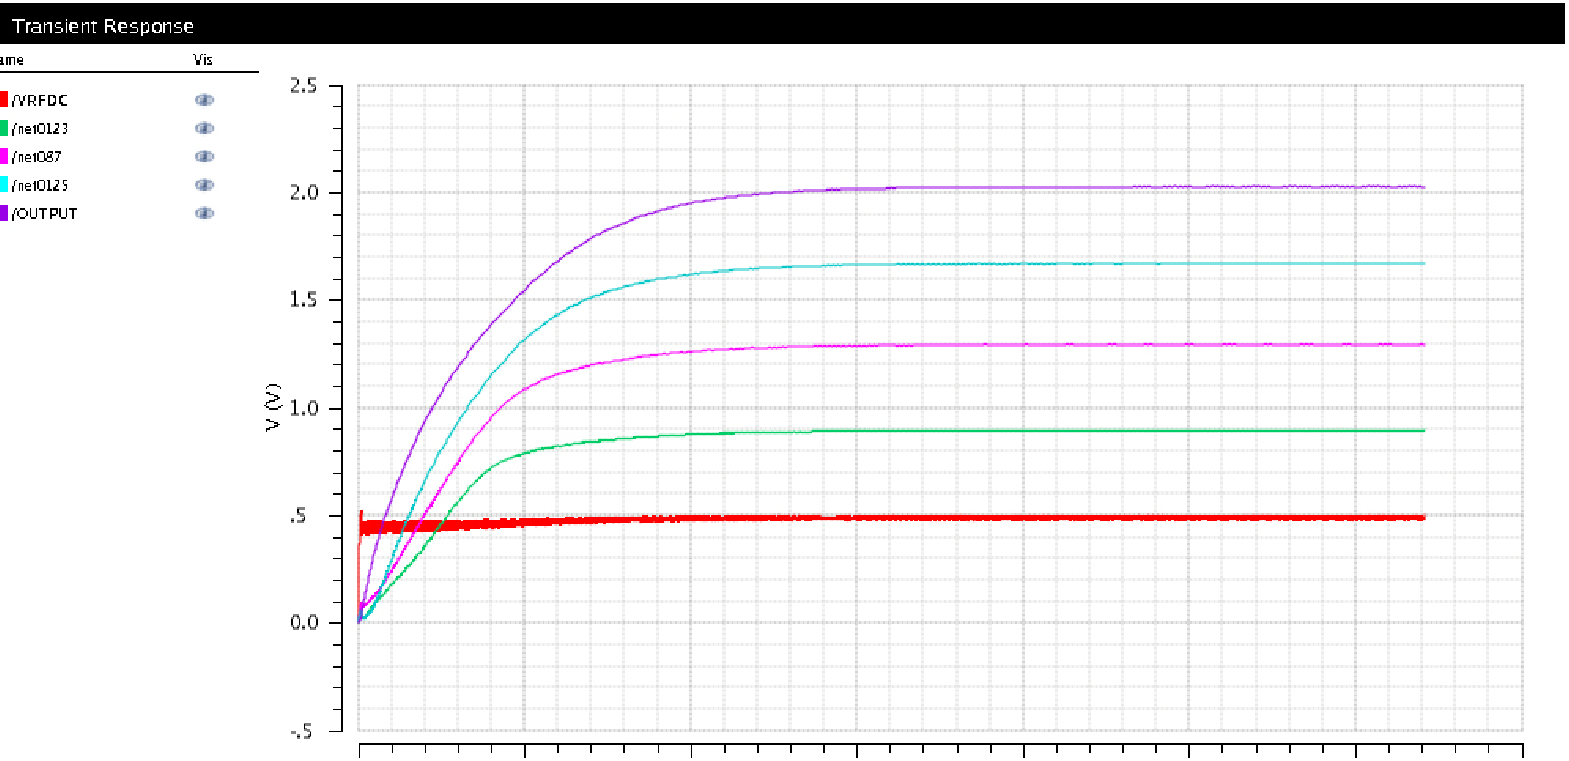
Sanjeev K, Manjunath M, TV Prabhakar, KJ Vinoy, Some Practical Considerations of RF to DC Converter using Low Vth CMOS Rectifier, Applied Computational Electromagnetic Conference, Guwahati, Dec 28-21, 2015

Full system simulations

- Output capacitor of RF-DC loaded heavily when clocks transition, so ripples exist in RF-DC output.
- Below 0.5V at clock transitions, above 0.5V between clock transitions
- Time step is 8ps for RF-DC simulation and DC-DC has to run for hundreds of µs or few ms, so simulations times are large.

Output voltage=2V across a load of 1.6MΩ, which gives

$$Efficiency = \frac{2^2/1.6\times10^6}{10^{-5}} = 25\%$$



Summary with IC Design

- Low Vth NMOS based DCP gives 42.3% efficiency.
- FGCCR gives 55% efficiency.
- The overall system efficiency is 25%.
- Higher than efficiency reported in literature for RF-DC converter operating at -20dBm, 2.4GHz in 130nm technology.

Bharat Hegde & Syed Younis 2015-16

Summary

- Most low power wireless terminals operate intermittently
- These require anywhere 50uW to about 10mW for their operation.
  - Batteries limited: cost, size, stored energy
  - Solar: not dependable through

- WPT and RF EH can enable wide use of IoT
  - Main challenges in the design is the low incident energy/power/voltage
  - High Quality factor components may help

- Several fabricated examples discussed here: All can transmit data to an aggregator wirelessly
  - Different standards implemented.

JOHN WILEY & SONS INC.
New York, Chichester, Toronto,Brisbane, Singapore

Preface

Static electricity became a fashionable science in the early 1700 century and several investigators drew a parallel between the sparks produced in the laboratories to that of lightning and thunder produced during foul weather. It is surprising, however, that even today with our highly advanced technology in electronics and space science we still do not know what causes thunderclouds to charge. The purpose of this book is to give a general overview on atmospheric electricity and to discuss several proposed charging mechanisms including resent important discoveries in atmospheric electrochemistry. The aspects of atmospheric electrochemistry becomes important when we realize that the atmosphere, due to the constant bombardment of cosmic rays, is ionized and behaves very much like an electrolyte. Electrochemical potentials are produced on material surfaces that are exposed to our ionized atmosphere and are as common as contact potentials generated when dissimilar conducting materials touch each other.

This book is not a review of the most current publications on atmospheric electricity but serves as overview of the basic problems still at large and the purpose is to try to inspire new fresh blood into the oldest field of electricity. Two excellent textbooks are recommended for those interest in a detailed picture of the electrical structure of our atmosphere: H. Israel, Atmospheric Electricity Vol. 1, (1970), and Vol.2 1973. J.A. Chalmers, Atmospheric Electricity, (1957).

The author is thankful to the Burndy Library; The High Voltage Research Institute, Uppsala University, Sweden and the High Voltage

Laboratory, T.U. Munchen for supplying historic illustrations.

Thanks is also due to Dr. John Hughes for initiating this work and for editing and facilitating the publishing of this book.

Boulder, January 1985. Lars Wåhlin

CHAPTER 1

HISTORICAL BACKGROUND

1.1 PRIMITIVE BELIEFS

An electric storm is one of nature's most spectacular phenomena, and its display of lightning and thunder has fascinated and frightened man throughout time. In ancient times it was believed that the great gods were responsible for hurling thunderbolts that could kill, upturn boulders, split trees or kindle fires. Man's early steps towards civilization began when he learned how to control fires started by lightning and use it against predatory animals. Tales from American Indians explain how the world was a cold place before the first fire was started by the thunderbird god. As recently as the 1870's German soldiers were convinced that magic power from the **donnerkeil**, or lightning stone, would protect them from French bullets. Lightning stones, believed to be spearheads of lightning bolts, could be found buried where lightning had struck. The lightning stones and their fragments were sold throughout Europe for many hundreds of years and were thought to protect from illness and evil. We know now that most of the stones and fragments found were old relics and artifacts from the Stone Age (Lundquist 1969).

Today we smile at old superstitions, yet we too bend to the mystery of lightning and its atmospheric implications, for modern man has yet to understand it.

1.2 EARLY ELECTROSTATICS

The first person on record to have suggested a relationship between electricity and lightning was an Englishman named D. William Wall (1708). He noted a similarity between lightning and the crackling sparks produced by the rubbing of amber. S. Gray (1735) and A.G Rosenberg (1745) both mention the similarity between lightning phenomena and electric fire produced by electricity machines in the laboratory; and in a book published in Leipzig 1746, J.H Winkler describes several resemblances between lightning and electricity. During this time improved electricity machines and Leyden jars became readily available and a new era of electrical science was born. Many more scientists, among them Benjamin Franklin, also questioned the nature of lightning, recognizing its similarity to the snapping sparks produced in the laboratory. "How loud must be the crack of 10,000 acres of electrified cloud!" exclaimed Franklin. In a letter to Dr. John Mitchel of the Royal Society in England, he enclosed a treatise, "The Sameness of Lightning and Electricity". According to Mitchel, the paper was read by the Society amidst laughter from its professed experts on electricity. Another paper dated July 1750, was sent to the Royal Society through a friend, a Mr. Collinson. In this paper Franklin described how electric "fluid" is attracted to pointed conductors. "Might not the same principles be of use to man in teaching him to protect houses, churches, ships and other structures from damage occasioned by lightning?" he asked. Thus the idea of the lightning rod was born.

As yet no experimental tests had been performed to prove that lightning was an electrical phenomenon. Franklin therefore proposed an experiment to answer the question once and for all. On a high tower or steeple a sentry-box was to be erected large enough to contain a man and an electrically-insulating platform. A long pointed rod or antenna would be attached to the sentry-box by means of insulators and would be connected to the insulated platform inside (Fig. 1). A man standing on the insulated platform would thus become charged from the rod when a thundercloud passed overhead. At will he might then draw sparks from his fingertips to the surrounding grounded wall.

e paſsing
fied, and

Fig. 1 Franklin’s proposed sentry-box experiment.

In principle it was just another lightning rod. From laboratory experiments Franklin knew that charge could be drawn from a nearby charged body by means of a pointed rod, which attracted electric "fire"

Fig. 2 D'Alibard's version of Franklin's sentry-box experiment.

The experiment was never to be performed by Franklin, due to the lack of financial aid, yet with time Franklin's ideas gained increasing approval from the Royal Society. In 1751 several of his papers were published in England in book form and soon thereafter translated into

French by the naturalist D'Alibard. So intrigued was D'Alibard by the sentry-box experiment that he decided to put it to the test himself. An experimental structure slightly different in design was erected outside Paris at Marly. (Fig. 2). By the 10th of May, 1752 D'Alibard (1752) had successfully determined that thunderclouds are indeed electrically charged.

In America a few weeks later Franklin, unaware of D'Alibard's success, performed his famous kite experiment. It was a poor man's experiment, simple and brilliant. It demonstrated that lack of financial help is an insufficient deterrent to genius. (One wonders if Dr. Franklin was advised, when looking for financial support, to go fly a kite). In his kite experiment Franklin not only confirmed the electrical character of lightning but also, more importantly, found clouds to be negatively charged at the base and positively charged on top, thus forming giant electric dipoles floating around in our atmosphere.

1.3 FRANKLIN VERSA NOLLET

It is interesting to note that Franklin spoke of positive and negative electricity. This is a product of his own theory on electricity and the concept of positive and negative charge is still being used today. Franklin envisaged electricity as a kind of fluid where a body could have either an excess or a deficit of fluid. For example, if a person standing on an insulated stool were to touch the glass cylinder of an electricity machine he would lose some of the fluid. A deficit or loss of fluid represents a minus state and excess fluid equals a plus state. The sum of positive and negative electricity is always nil. The plus state of the fluid was determined by Franklin as follows: A positively charged pith ball would snuff out the flame on a candle i.e. the flame will retreat from the ball while the ball is trying to rid itself of excess fluid. A modern explanation is that the flame, which contains a great number of positive ions produced by the heat and combustion, will be repelled by any other positive charge in its vicinity. One consequence of Franklin's theory is the convention of labelling the direction of electric current. Although in metals the charge is carried by electrons flowing from minus to plus, we are now forced to assume that electric current or charge is flowing from plus to minus in order to keep things algebraically consistent.

The Abbè Nollet (1700-1770) of Paris was the authority on electricity in Europe during the time of Franklin's discoveries. Nollet was aware of two different kinds of electricity, namely glass electricity and resin electricity. He believed that the two different kinds of electricity were liquid streams flowing in and out of electrified bodies in opposite directions, effluence and affluence. Nollet maintained a very negative attitude towards Franklin's ideas on electricity and especially to the lightning rod. This is perhaps one reason why it took so long for the lightning rod to become established in Europe. The Abbè Nollet, however, was a master of experimental electricity. He often performed electricity demonstrations before Louis XV and his court. A typical demonstration would be to pass a high voltage static charge from a Leyden jar, through seven hundred monks holding hands, causing them to jump in perfect unison, to the King's delight. Nollet was often criticized for activities such as this. His theories on electricity were eventually abandoned in favour of Franklin's ideas which, to a certain extent, still are used today.

1.4 THE LIGHTNING ROD

A year after the famous tests of D'Alibard and Franklin a Russian professor named Richmann attempted to repeat the sentry-box experiment. The result is pictured in Fig. 3. Professor Richmann was killed instantly when lightning struck his antenna on the roof of the laboratory in St. Petersburg. As a result of this accident the general public grew skeptical of the lightning rod as a protective device.

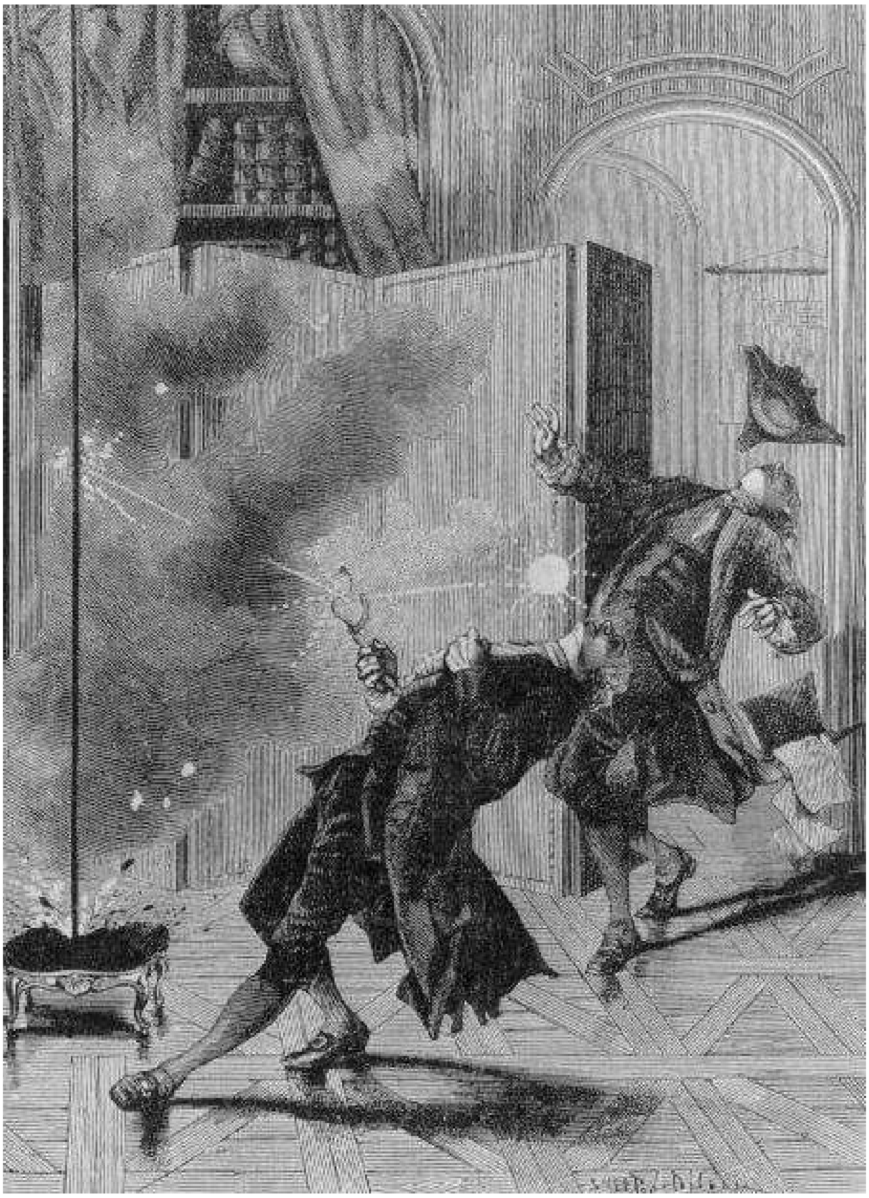

Fig. 3 Professor Richmann is killed when lightning strikes his experimental antenna in St. Petersburg, 1753.

Did not the death of Professor Richmann prove that lightning rods attract lightning? Some twenty years later Europeans finally accepted Franklin's invention, but the arguments against it were many. One such argument, advanced by a number of scientists spearheaded by Nollet, ran as follows:

If a large structure like a church steeple is not spared by lightning,

> how much larger must the lightning rod itself be to withstand the devastating power of a severe bolt?

The argument seemed valid at the time, for church steeples literally exploded when struck by lightning (Ohm's Law had not yet been formulated). The electric resistance of a church steeple is perhaps one megohm, and since the average lightning bolt carries about 25,000 amperes, it dissipates a peak power of $R \times I^2 = 6.25 \times 10^8$ megawatts. Although the duration of the lightning bolt is short, its total energy is considerable. The function of the lightning rod is, of course, to lower the resistance across the structure a million or more times and thus to permit the energy to dissipate into the ground.

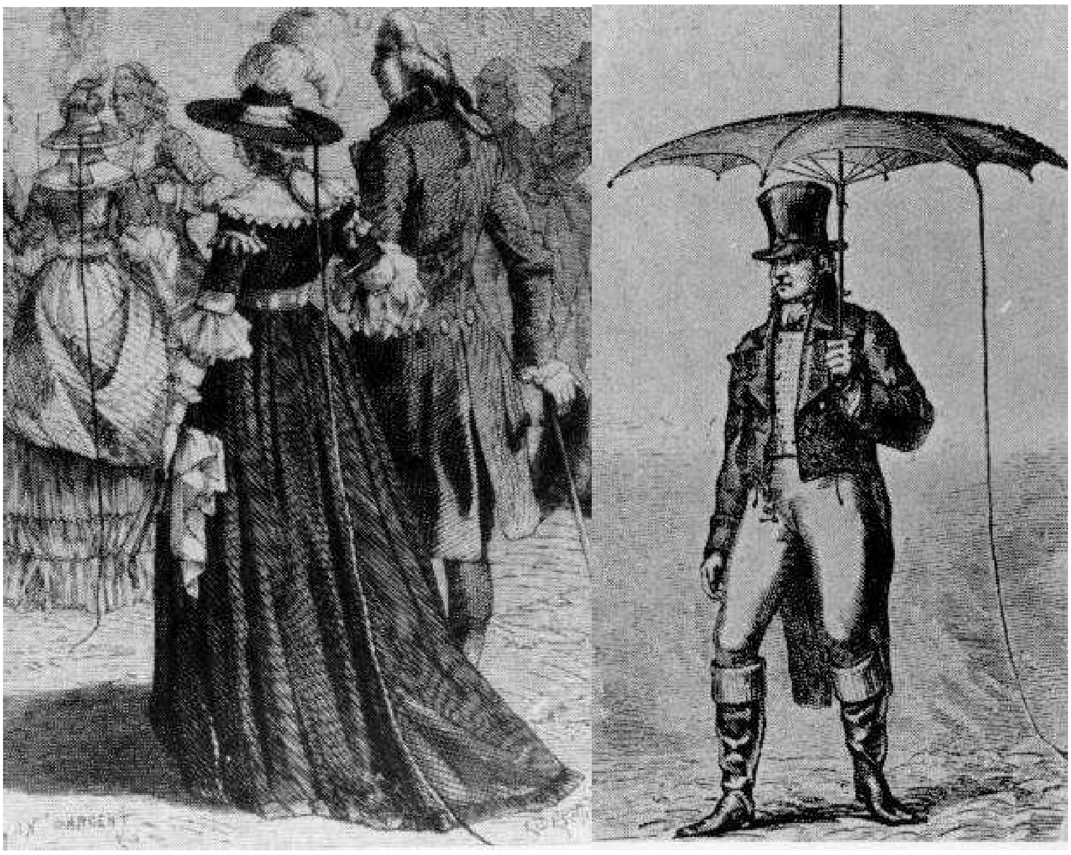

Fig. 4 Hat pin and umbrella lightning rods (Paris, 1778).

Eventually the lightning rod became a common sight on both sides of the Atlantic. Europeans, who had once strongly rejected the notion, embraced it with an enthusiasm that led to extravagant measures for protecting life and limb from the perils of lightning (Fig. 4).

Ironically, Europeans today are occasionally amused by the different shapes and designs of American lightning rods which they feel are costly and only of psychological importance, see Fig. 5. (Muller-Hillebrand 1963).

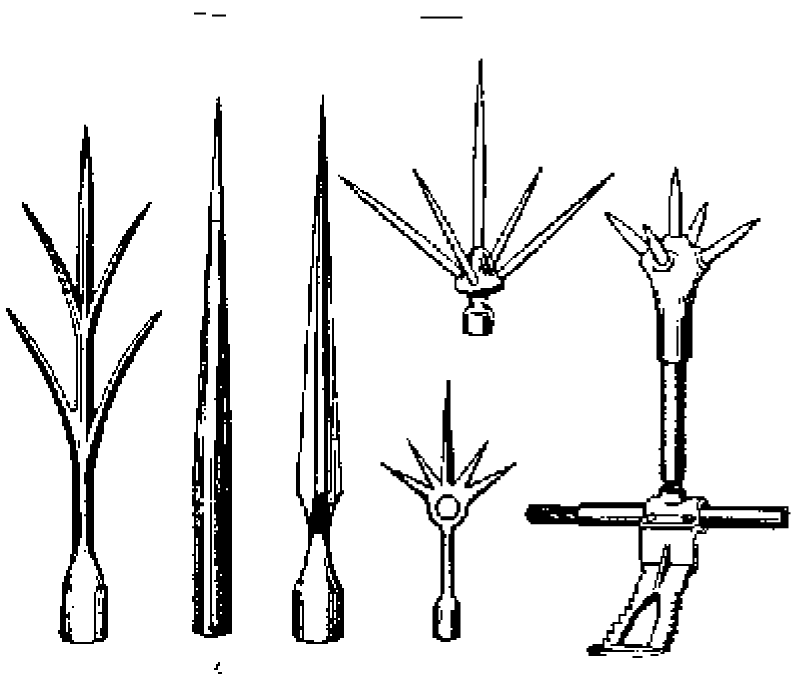

Fig. 5 Points according to American standards (1959) not cheap and only of psychological importance.

1.5 LATER DEVELOPMENTS

The D'Alibard-Franklin experiments were repeated by many investigators and most noteworthy is perhaps L. Lemonnier (1752) who, with his more sensitive apparatus, discovered that weak electrical charges could be detected in the atmosphere in the absence of clouds. He also noticed a difference in electric intensity during night and day. The discovery of Lemonnier is important because it gave birth to a new field of research in atmospheric physics, namely "Fairweather Electricity".

In 1775 the Italian scientist Beccaria (1775) confirmed Lemonnier's findings with one important addition, that pointed rods and insulated wires suspended in the atmosphere became positively charged relative to the earth's surface during fine weather, under cloud-free skies. This meant that an electric field is present in the atmosphere even when no thunderclouds are near. Beccaria also noticed a polarity reversal when a thundercloud passed overhead, indicating the introduction of negative charge from above. Thus he substantiated Franklin’s earlier finding that thundercloud are generally charged negatively at the bottom and positively at the top, an observation that can be readily confirmed today.

The first notable attempt to explain the origin of fairweather electricity was made by Lord Kelvin (1860). He was first to envisage the fairweather field as electric field lines which must stretch from the earth's surface and terminate on charges in the atmosphere. The direction of the field is towards the earth's surface. He theorized that the charged atmosphere forms a giant capacitor with the earth's surface. The capacitor model was later expanded by Kennely and Heavyside (1902) who suggested that the conducting layer in the atmosphere is the ionosphere which forms a spherical capacitor with the earth's surface where each "plate" of the capacitor carries a charge of nearly one million coulombs. A charge of this magnitude will, of course, produce an electric field of a few hundred volts per metre at the earth's surface. This is the normal value of the persisting fairweather field and Lord Kelvin, not knowing what process had charged the capacitor plates, at least seemed to have a reasonable idea explaining the structure of the fairweather field. Unfortunately for the attractive theory, later discovery of ions and cosmic rays proved the atmosphere to be electrically conducting. Lord Kelvin's capacitor model would therefore lose its charge in less than 10 minutes at a rate of nearly 2000 coulombs per second (=2000 amperes). It should be mentioned that C.A. Coulomb, the father of the electrostatic force law, discovered in 1785 that air is slightly conducting, an observation that was not understood at the time.

Where does the atmospheric fairweather charge come from? How is it replenished at the rate of 2000 coulombs per second? Many answers have been proposed, the most popular being that of C.T.R. Wilson 1n 1925. Wilson suggested that all thunderstorms around the world are electrical generators which by their violent discharges continusally supply electricity to the earth-ionosphere system. More recent evidence, however, weighs heavily against this evocative idea. Insufficient charge is available from worldwide thunderstorms to drive such a global electric circuit. Furthermore, data presented by Imyanitov and Chubarina, among others, demonstrate that annual variations of the fairweather field are not in phase with typical thunderstorm activity throughout the world for the same period. Despite the argument against Wilson's proposal and the lack of evidence to support it, many investigators still favour the idea since, until very recently, there has been no other explanation available. Now there is a new theory in competition with Wilson's concept based on the electrochemical properties of the atmosphere. This theory is discussed in Chapters 2 and 3.

Serious research on lightning and thunderclouds started late. With the birth of electric power in the early 20th century and the many power failures due to lightning, a better understanding of lightning and thundercloud charging was necessary. Charles Proteus Steinmetz, a German immigrant to America who worked as an engineer at General Electric Laboratories to develop lightning arrestors, might be considered as one of the early pioneers of modern lightning research. His work led to the construction of high-power high-voltage generators which could simulate lightning flashes. The machines consisted primarily of a large capacitor bank which was charged by a high voltage transformer via rectifiers or diodes. For the first time research could be performed on large electric discharges under controlled conditions. Much information was gathered by Steinmetz and his lightning machine which has helped us understand electric transients and has aided in the design of lightning protectors. The invention of the oscilloscope increased our knowledge on the lightning discharge because of its fast response to electrical transients. H. Norinder at the University of Uppsala High Voltage Research Institute was first to obtain such oscilliograms from lightning surges in 1925. Parallel with electric research during the first part of the 20th century was the development of high speed cameras which would record the optical properties of lightning. The first camera suitable for recording the rapid changes in lightning flashes was created by Sir Charles Boys who himself, unfortunately, did not obtain any satisfactory pictures of lightning flashes. It was not until 1933 that the Boys camera became a main contributor to what we now know about lightning discharges. It was B.F.J. Schonland and his team in South Africa who discovered the different sequences of a lightning flash with the aid of a Boys camera (Fig. 6) and revealed the initial process of the stepped leader. Boys' pictures show that a bright-tipped leader works its way down from the cloud in steps. When the leader gets near ground it is met by the main return stroke which carries the main discharge current through the ionized conducting path provided by the leader. Normally the stepped leader is invisible to the naked eye and only the main stroke can be seen. The return stroke therefore, appears to start from ground explaining the saying that lightning travels from ground up.

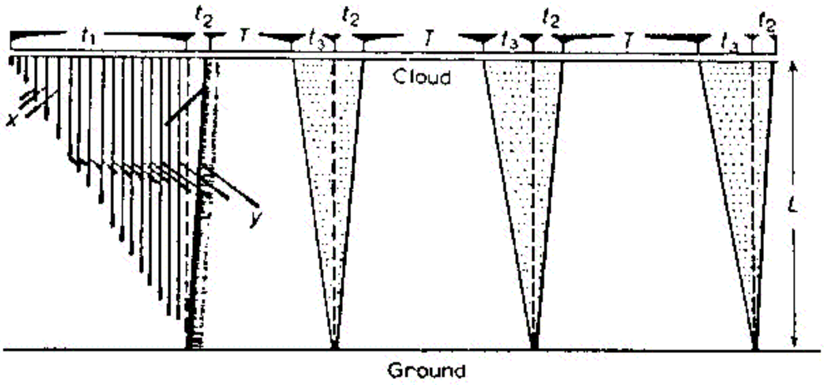

Fig. 6 Boys' camera photograph of cloud to ground discharge.

At the present time much is still unknown about atmospheric electricity and its origin. What mechanism is responsible for the build up of cloud charges and what generates the electric fairweather field? How is charge drained from a cloud or how does the lightning bolt connect up to all the myriads of charged drops in the cloud? These are still valid questions and, in the author's opinion, is the reason why Atmospheric Electricity is one of the most challenging fields in science today.

CHAPTER 2

THE ELECTRIC STRUCTURE OF THE ATMOSPHERE

2.1 IONS

The existence of ions in the atmosphere is the fundamental reason for atmospheric electricity. An absence of ions would mean zero electric field in the atmosphere and most probably no thunderstorms or lightning. The concept of positive and negative ions as charge carriers in the atmosphere was first put forward by J. Elster and H. Geitel (1899) in order to explain the electric conductivity of air. Much work has since been done on ions and their role in atmospheric electric phenomena. Today we know there are mainly three classes of ions, namely small ions, intermediate ions and large ions. Most important are the small ions since their higher mobility allows them to take a more active part in the transfer of charge throughout the atmosphere. The mobility of ions can be measured in metres per second per volt per metre which signifies the velocity that an ion will reach when subjected to an electric field of one volt per metre. For small ions the mobility is of the order of 0.0001 with a slight edge of the negative ion over its positive counterpart. In fact, the negative to positive mobility ratio of small ions is about 1.25 (Wåhlin 1985) which is a paradox since negative ions are believed to be more massive than positive ions. One explanation (Papoular, 1965) is that for part of its lifetime a negative ion is really an electron jumping from molecule to molecule. Molecules such as NO and NO_2 are believed to dominate the negative small ion population while oxonium and water might make up the positive small ions in the atmosphere. Their true molecular structure and mass are not well known because it is difficult to get spectroscopic mass analysis of small ions in the lower atmosphere. The problem is their relative short life time, about 100 seconds, which is much shorter than the transit time required for molecules or ions to reach the source end of a mass analyser.

The ionization in the lower atmosphere is mostly caused by cosmic rays and natural radioactivity. Ions are also produced in and near thunderclouds by lightning and corona processes. Cosmic rays originate from solar flares and other galactic objects such as supernovas and exploding stars. One interesting thought is; do stellar events affect our lives here on earth? We know that cosmic rays are by far the major ion producers in the lower atmosphere and if thunderstorms need ions to feed on in order to charge, we certainly would not have thunderstorms if there were no cosmic rays. Ancient man would not have had access to fires and the many thousands deaths each year from lightning strokes would have been avoided.

Cosmic rays originate from deep space and usually consist of very high-velocity atoms that have been stripped of their orbiting electrons. There are also electrons present in space that travel with near-light velocities, but such particles are usually absorbed at very high altitudes in the earth's atmosphere. However, heavy cosmic rays penetrate the atmosphere quite far and often reach the earth's surface. During such an encounter numerous secondary electrons are produced (electron showers) along its track from ionizing collisions with atmospheric molecules. The secondary electrons in turn might ionize a fair amount of molecules themselves before they slow down and attach themselves to atmospheric molecules to form negative ions. The result is that one cosmic particle could be responsible for the creation of as many as one billion ion pairs. Fig. 7 shows the rate of ion production by cosmic rays as a function of altitude (Wåhlin 1994). The average production

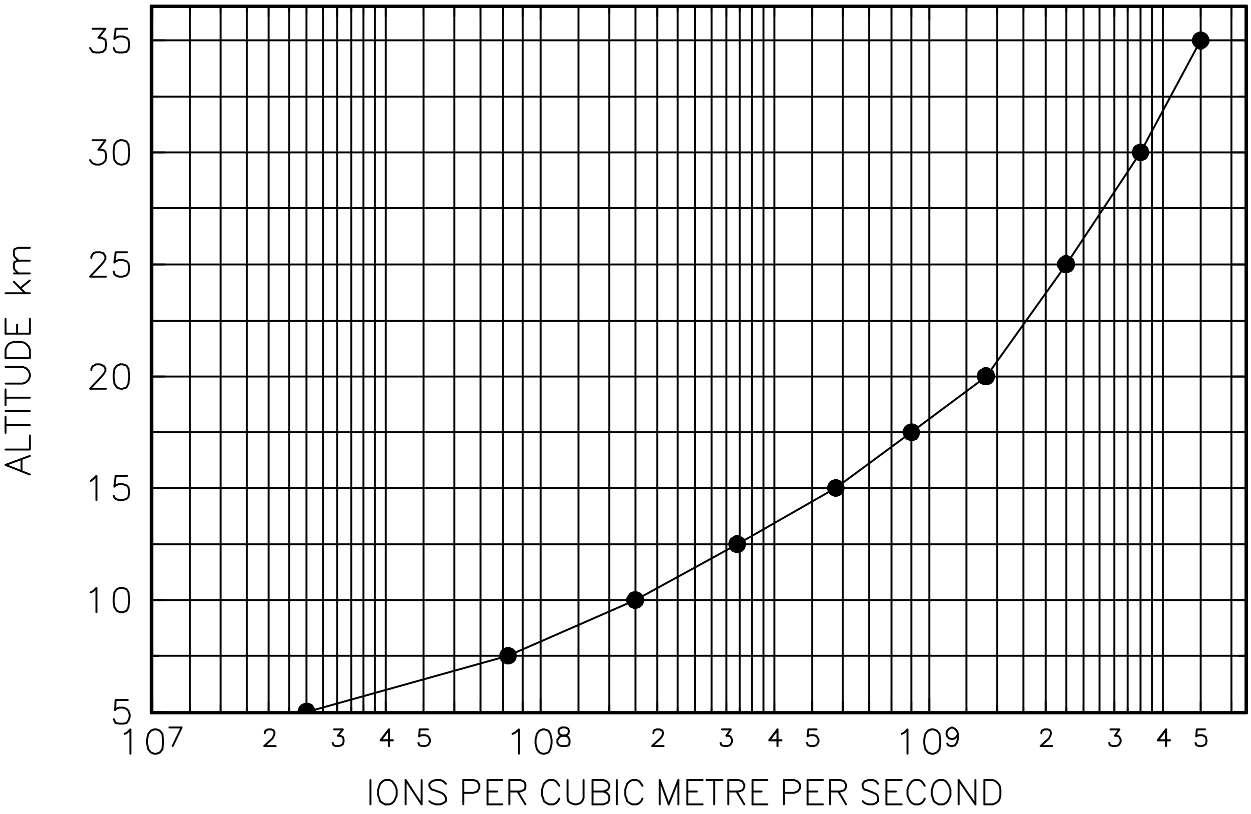

Fig. 7 Ion production as function of altitude.

rate at sea level is about ten million ion pairs per cubic metre per second. However, the average ion population at any given time is nearly one hundred times more, and ion mobility with altitude as air gets thinner has a drastic effect on the electric structure of the atmosphere. Typical conductivity data as a function of altitude are shown in Fig. 8. The conductivity is the inverse of specific resistance and is usually measured with a Gerdien cylinder (Gerdien 1905). The Gerdien apparatus consists of a cylinder with a coaxial mounted electrode (see Fig. 9). Air is drawn through the cylinder at a velocity of a few metres per second by means of a fan. The centre electrode is biased to a few volts via a sensitive electrometer. The amount of current registered on the electrometer relates to the amount of ions per unit volume of air. Care must be taken not to over-bias the inner electrode in order to avoid saturation currents. When properly calibrated, the Gerdien instrument can read both the positive and

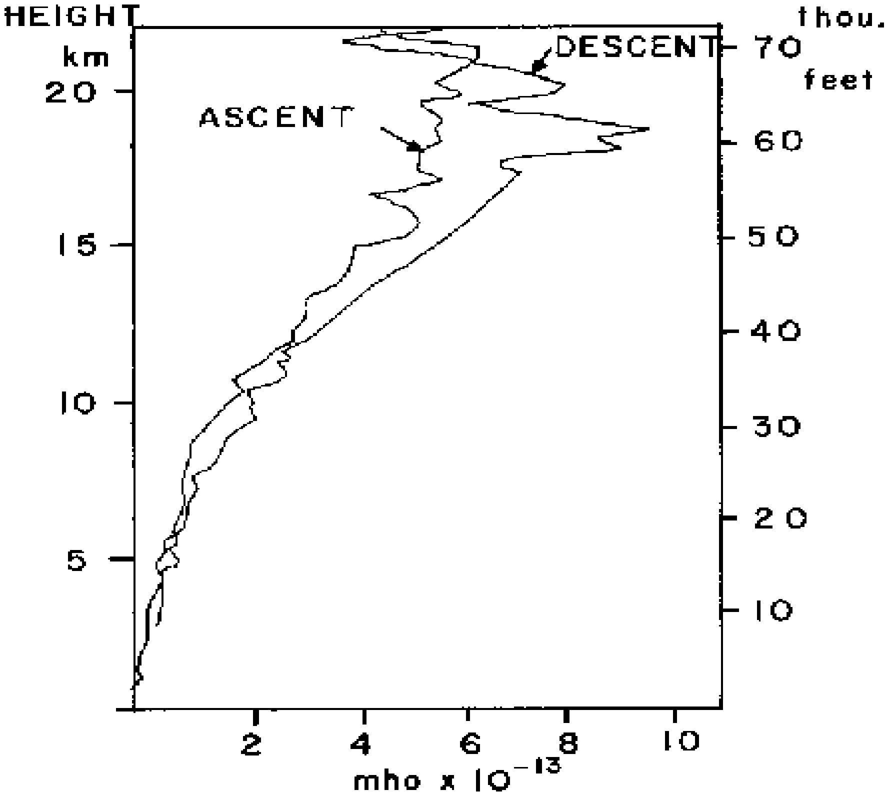

Fig. 8 Conductivity as a function of altitude (Rocket data).

negative conductivity of air depending on the polarity applied to the centre electrode. A typical ion current plot is shown in Fig. 10 where two identical Gerdien cylinders were tested, the only difference being that one was made of stainless steel and the other of aluminium. Three important features appear from the results shown in Fig. 10. First, the slopes of the two curves are different for negative and positive ion currents. This is due to the difference in ion mobility between negative and positive ions; therefore, the ratio of the slopes equals the ratio of the ion mobilities. Secondly, there is still a negative ion current going to the centre electrode when the electrode is at zero volt bias. Thirdly, the negative ion current at zero bias is higher for a Gerdien instrument made of aluminium than stainless steel. In order to obtain a zero ion current on the electrometer one needs to bias the stainless steel at 0.4 volts and the aluminium at about 1 volt. These results led to the discovery of electrochemical potentials in the atmosphere (Wåhlin 1971) which appear on material surfaces in contact with ionized air. The

reason why stainless steel and aluminium have to be biased at different positive potentials, to achieve zero ion current, is to cancel out

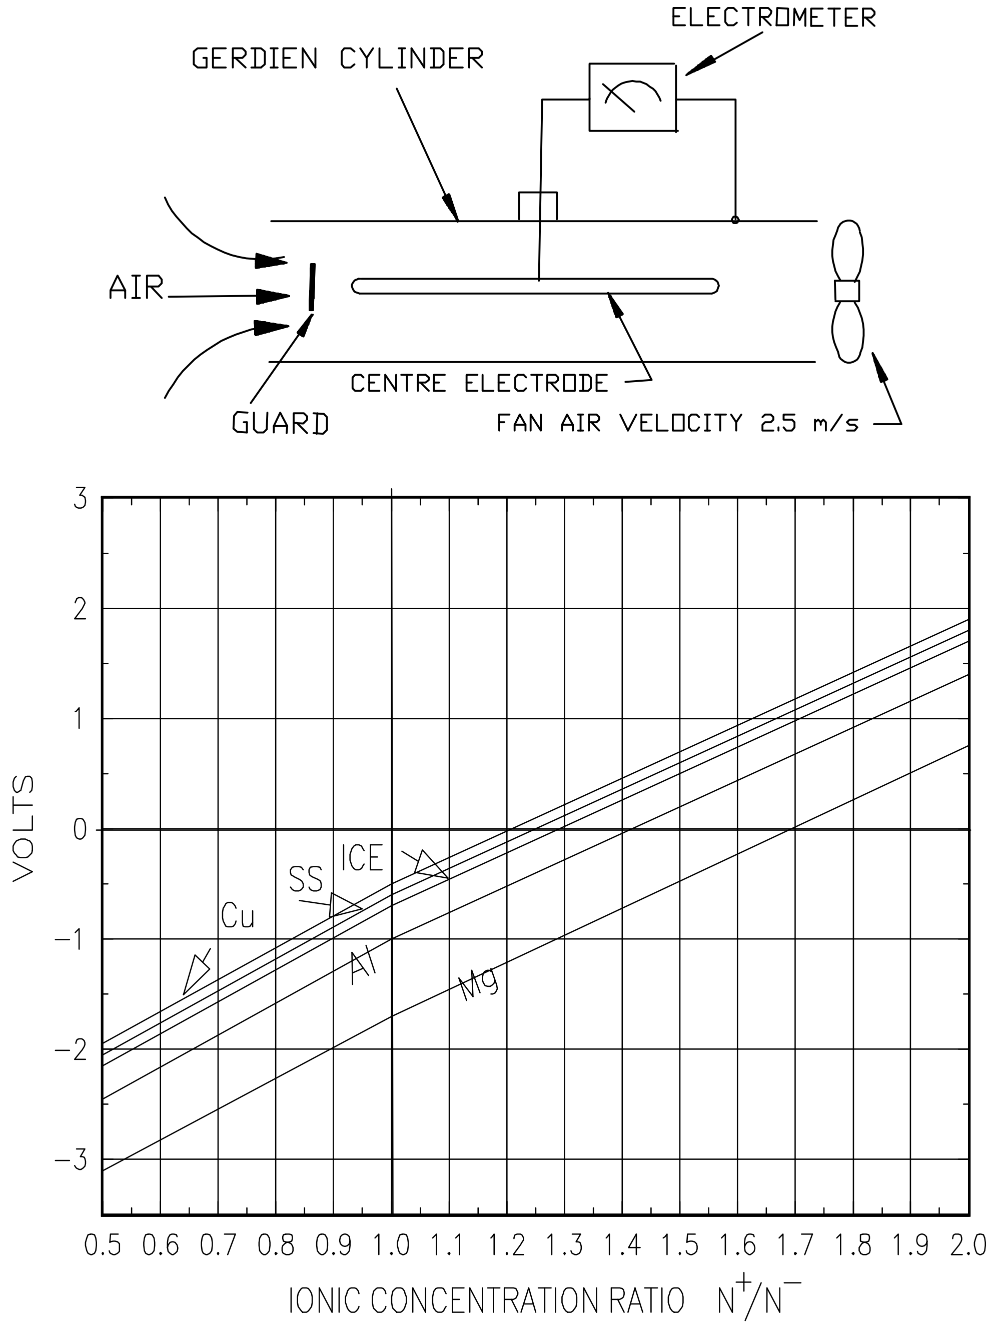

Fig. 11 Electrochemical equilibrium potentials for different materials as a function of ion concentration ratios.

the electrochemical or oxidaion-reduction potentials which are characteristic of each material and appear when exposed to an ionized environment. The effects of contact potentials are eliminated since both the inner and outer electrodes of the Gerdien instrument are made of the same material. The graphs in Fig. 11 show electrochemical potentials on different materials as a function of positive to negative ion concentration ratio. Electrochemical and contact potentials will be discussed further in Chapter 3.

2.2 THE FAIRWEATHER ELECTRIC FIELD

The fairweather electric field discovered by Lemonnier and Beccaria (see Chapter 1.2) is almost entirely due to the excess of positive ions over negative ions in the atmosphere.

The fairweather field is best understood if we assume that the earth's surface has absorbed a certain number of negative ions from the atmospheric ion pair population. It will create a slight excess of negative charge on the earth's surface with an equal excess of opposite charge in the form of positive ions left behind in the atmosphere. If we imagine that each captured charge on the earth's surface will produce

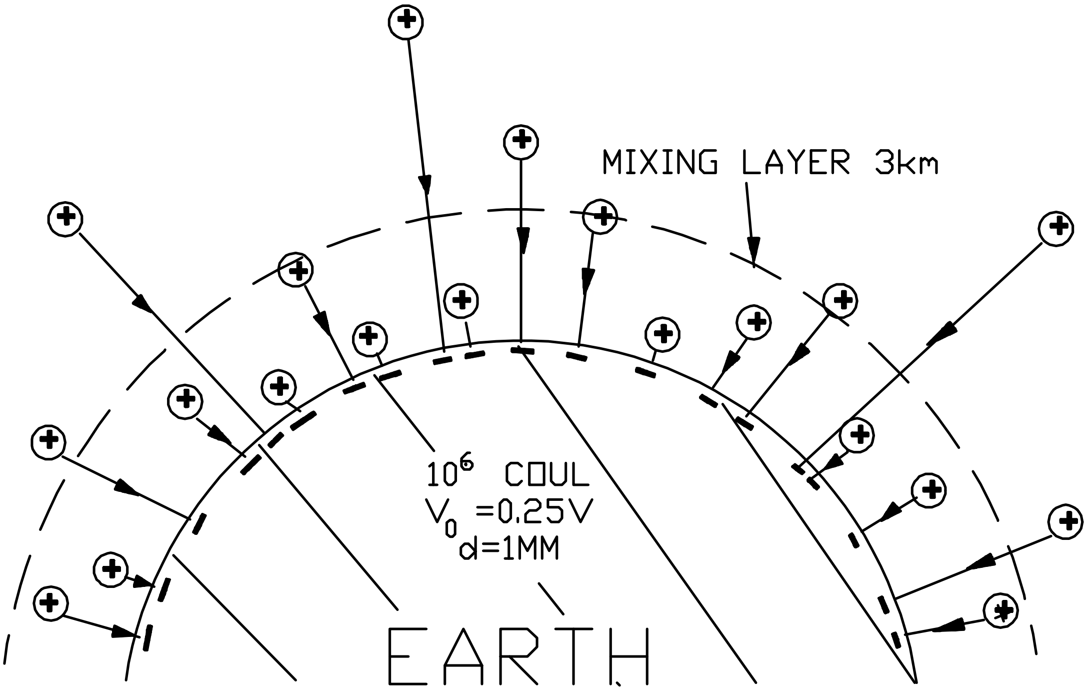

Fig. 12 The fairweather electric field in the atmosphere.

an electric field line which must terminate on a positive excess ion left behind in the atmosphere one obtains a fairly accurate picture of the electric fairweather field in the atmosphere, such as shown in Fig. 12. The excess positive ions are more or less uniformly mixed in the lower 3 km of the atmosphere which, to the meteorologist, is known as the "Austauch" or mixing region. The mixing is produced by convection and eddy-diffusion and the ionic distribution follows the mixing patterns of other constituents in the atmosphere such as radon for example. Radon is a radioactive gas emitted by the earth's surface and is constantly released into the atmosphere. Fig. 13 shows the vertical distribution profile of excess positive ions compared to that of the radon gas. The positive ion distribution is determined from electric field measurement at varying altitudes and by applying Poisson's equation. The radon profiles are obtained from airborne radioactive counters that detect the daughter products of the decaying radon gas.

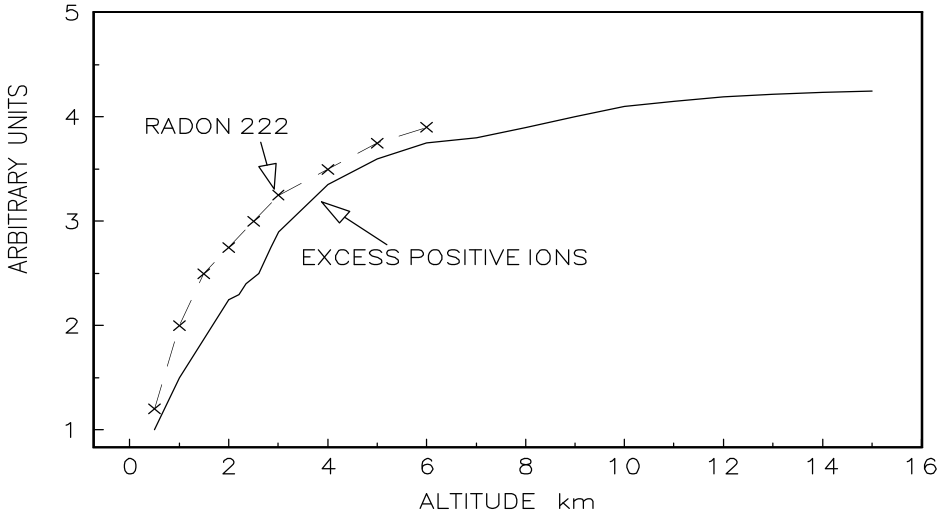

Fig. 13 Relative distribution of radon atoms and excess positive ions as a function of altitude.

The number of field lines per unit surface area produced by the positive charge or space charge above the earth's surface is also a measure of the electric field strength. Obviously the electric field strength reaches a maximum at the earth's surface since it contains the largest number of field lines per unit area. The average field strength at the earth's surface is on the average 100 volts per metre and decreases to less than 10 volts per metre at an altitude of 3 km. If one integrates the electric field as a function of altitude one obtains the total potential difference V at different heights. A typical value of V at 3 km is 200 kV with respect to the earth's surface. The total charge Q on the earth's surface is

$$Q = AE\varepsilon_0 , \tag{1}$$

where A is the surface area of the Earth, E the electric field strength at the surface and ε_0 the permittivity of free space ($\varepsilon_0 = 8.85 \times 10^{-12}$ Farad m^{-1}). The total energy of the fairweather field is

$$W = \tfrac{1}{2} VQ . \tag{2}$$

Fig. 14 shows the total electric energy, charge and potential in the atmosphere as a function of altitude. More than 90% of the energy is confined to an altitude below 3 km which together with the charge distribution curve in Fig. 13 seems to indicate that convection and eddy diffusion play a predominant part in the distribution of the fairweather electric field and that the bulk of its energy is distributed throughout the mixing region by the so called "Austauch Generator" (Kasemir 1950).

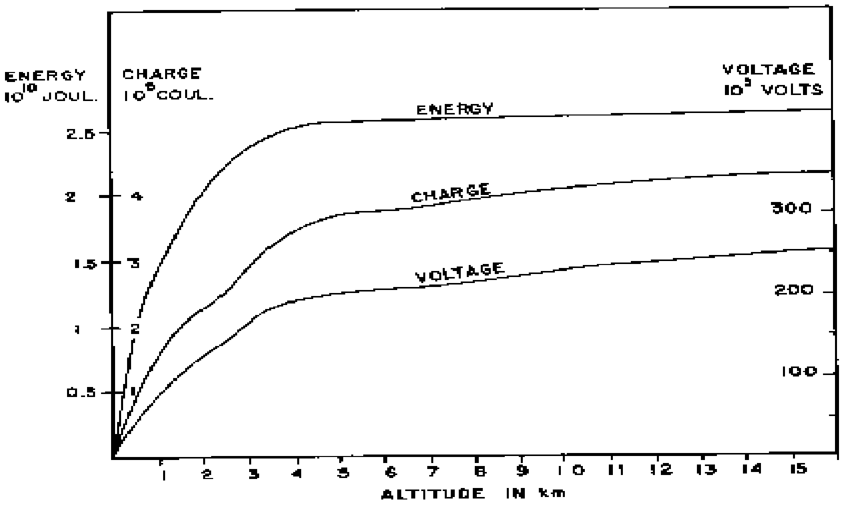

Fig. 14 Electric energy, charge and potential vs. altitude.

One crucial question still remains to be answered. What causes the positive space charge in the atmosphere and how is the opposite negative charge maintained on the earth's surface? As mentioned before there are two schools of thought on this one in which all thunderstorms around the world are believed to charge the earth-atmosphere system (Wilson 1929) and a more recent theory proposed by the author (1973) which considers the electrochemical effect as a charging mechanism where negative atmospheric ions are preferentially captured by the earth's surface leaving a space charge of positive ions behind in the surrounding atmosphere. Both theories might be supported by the evidence of a small systematic diurnal variation in the fairweather field, which is believed to be related to the world-wide atmospheric convection activity. The effect was first discovered in Lappland 1905 by Simpson whose findings were later augmented by Hoffmann (1923) and Mauchly (1923). The effect is

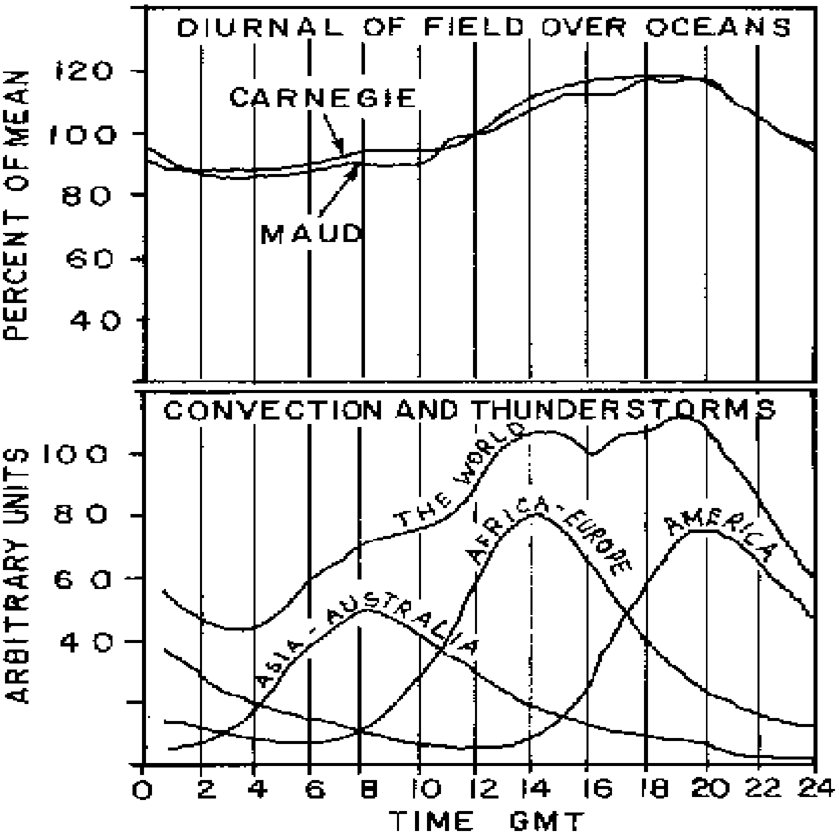

Fig. 15 Diurnal variations in the fairweather field compared to world-wide convection.

illustrated in Fig. 15 where the average variation in the world-wide potential gradient is compared to the estimated world-wide convection activity at different times of day (by GMT). The top graph shows the global variations in the electric field measured at sea in the absence of local disturbances such as pollution, fog, etc. The top graph seems to coincide with the lower graph which gives an estimate of the world-wide convection activity produced by the heat of the sun during a diurnal period. The steady convection over oceans, however, is thought to smooth out the electric field variations as is evident from the top graph. Before discussing the electrochemical and global thunderstorm circuits as possible generators of the fairweather field, it is necessary to examine the global leakage current and its implications.

2.3 THE AIR TO EARTH CURRENT

As already mentioned, the atmosphere is conducting and the earth's electric potential or field must cause a current to flow in the atmosphere. Since there is an excess of positive ions residing in the atmosphere and an opposite negative charge bound on the earth's surface, charge must flow to earth in the form of a positive ion current.

Direct measurements of electric currents in the atmosphere are difficult if not impossible. Therefore, ion current values at different altitudes are almost always computed indirectly from conductivity and electric field data by the use of Ohm's law. Direct current measurements can be made, however, at ground level by isolating a portion of the earth's surface and measure the charge collected over a given time. Several methods can be used (Wilson 1906, 1916, Simpson 1910, Mühleisen 1953 and Kasemir 1951) but in almost all cases the indirect current gives a value often twice as large as the direct method (Lutz 1939, Israel 1954). Whipple (1932) pointed out that the discrepancy in currents can be explained by the fact that there is always convection and eddy diffusion in the atmosphere which will mechanically move charges upwards in the atmosphere thus generating a mechanical or convection current in the opposite direction of the leakage current (the Austauch generator). As later explained, the question whether or not the convection and leakage current on the average are equal is crucial to the electrochemical charging theory and is a problem which has not yet been settled.

From direct current measurements it is possible to estimate the total fairweather current over the whole earth to be nearly 2000 amperes which corresponds to a current density of about 4×10^{-12} amperes per square metre. Other charge transfer mechanisms in the atmosphere of importance are point discharges, precipitation currents and lightning discharges.

2.4 POINT DISCHARGE CURRENTS

It is difficult to determine the total charge brought to the earth's surface by means of point discharge currents under electrified clouds. Wormell (1930) has made some estimates from the amount of charge brought down by a single point over a period of 4 years. He made a guess that the total point discharge current around the world brings negative charge to the surface at a rate of about 1500 amperes which would supply about 75% of the total fairweather leakage current. Other investigators give slightly lower values for the average point discharge current but not less than 25% of the fairweather current. The source of point discharge currents are the electrified clouds which of course also bring charge to ground by lightning. The point discharge current is, to a certain extent, canceled by the large amount of positive lightning flashes to ground and through positive charge reaching the earth's surface by precipitation.

2.5 PRECIPITATION CURRENTS

The electricity of precipitation has played an important role in atmospheric research due to the belief that charging of precipitation particles in some way must relate to whatever charging mechanism is active in clouds. Paradoxically, this is not always true because the final charge on a cloud drop is determined in the space between the cloud base and ground and is usually of opposite sign to the charge of the cloud base where it came from. This peculiar phenomenon is called the mirror-image effect and is demonstrated in Fig. 16 by the two curves which show the change in electric field strength and amount of precipitation charge reaching the earth's surface as a function of time.

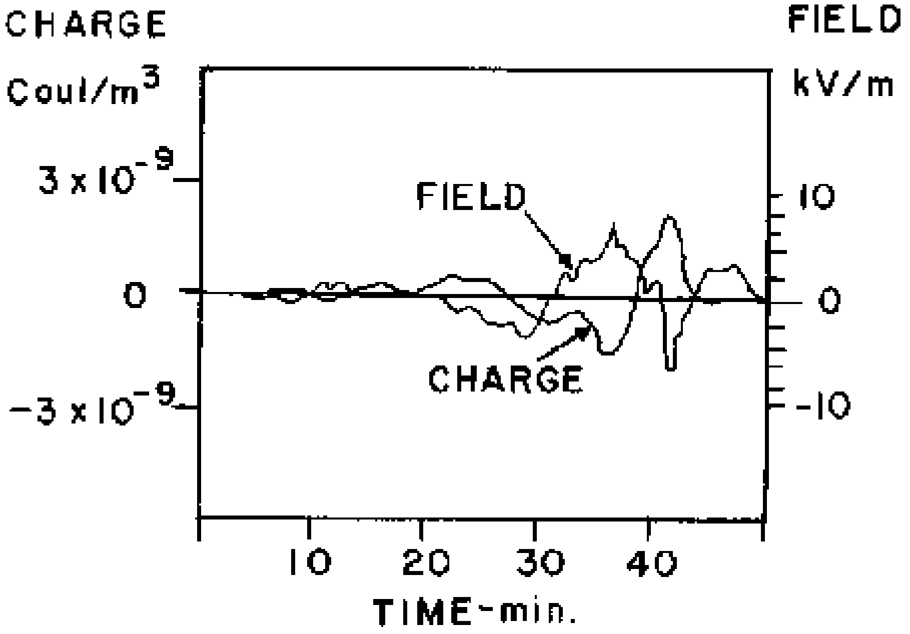

Fig. 16 The mirror-image effect.

One can easily see that when the electric field goes negative (negative charge in the cloud base) the precipitation current becomes positive and vice versa. As pointed out by Chalmers, a drop must take several minutes to fall from the cloud base to ground. Since the precipitation charge changes with the potential gradient below the cloud, it must mean that the drops also obtain their final charge below the cloud or very near ground. The electrochemical charging process can possibly explain the mirror-image effect if one assumes that the positive to negative ion concentration ratio near ground is affected by the strong electric field under the cloud. For example, a positive charge on the earth's surface, caused by a strong negative cloud charge above, would attract and remove part of the negative ion population near the surface. The result would be a higher than normal positive to negative ion concentration ratio at lower levels. When the positive to negative ion ratio exceeds 1.2 (see Fig. 11) it will produce a positive electrochemical potential on water drops falling through such a region as demonstrated by the Gerdien apparatus experiments in section 2.1. On the other hand, a positive cloud charge above would reverse the effect because drops now fall through an environment containing a higher negative to positive ion concentration ratio which will generate negative electrochemical charges on their surfaces. Other explanations of the mirror-image effect take the Wilson charging mechanism into consideration. This charging mechanism is based on the idea that rain drops become electrically polarized when immersed in an electric field such as under an electrified cloud. A negative cloud charge above will induce a positive charge on the top surface of a drop and the bottom surface will acquire a negative charge induced by the positive charge on the earth's surface. The total net charge on the drop, however, would remain zero. As the drop falls through the ionized region below a cloud it would preferentially sweep up positive ions by its negatively-charged bottom. Calculations, however, show that the Wilson mechanism is too feeble to account for the amounts of charge normally collected by drops (the Wilson charging mechanism is discussed further in Chapter 3). In contrast to rain, precipitation currents carried to ground by snow are usually always negative under potential gradients between ±800 V/m (Chalmers 1956). The total precipitation current around the earth is estimated to be about +340 amperes.

2.6 LIGHTNING CURRENTS

The charge brought to earth by lightning is estimated to average –340 amperes which would cancel the precipitation current. It must be remembered that a mean current of –340 amperes represents the excess of negative charge over positive charge reaching ground by lightning and that the ratio of negative to positive ground strokes equals about 10:1. The average current in a negative lightning stroke to ground is about 25,000 amperes but the total charge averages only 25 coulomb. Positive ground strokes usually carry as much as 10 times more charge and current than do negative strokes although they are outnumbered by 10:1. The ratio of negative to positive ground strokes seems to vary with global location.

It is believed that about 2,000 thunderstorms are active at one time around the earth which amounts to a total number of 50,000 thunderstorms per day.

2.7.1 THE ELECTRIC BUDGET

Where does the energy of nearly 200 million watts come from that is required to maintain the earth-atmosphere electric fairweather field? Are thunderstorms generating the fairweather field by leaking off positive charge from cloud tops to the conducting ionosphere and by bringing negative charge to earth in the form of negative ground strokes and point discharge currents? Or is the electric charge on the earth's surface maintained by the electrochemical charging mechanism in close collaboration with convection and eddy diffusion? These are some of the basic questions that are still in need of answers. Both mechanisms are, in the author's opinion, certainly capable of supplying enough charge and energy to the earth-atmosphere system, but new ideas and more sophisticated measuring techniques are needed in order to find the right answers.

2.7.2 THE GLOBAL THUNDERSTORM CIRCUIT

The concept that all thunderstorms around the world generate charge to the earth-ionosphere system was first suggested by C.T.R. Wilson in 1920. The diagram in Fig. 17 shows the global thunderstorm system as interpreted by Wilson. Electric field lines extend from the top of a cloud to the highly conducting upper layers of our atmosphere (50km and higher). Charge is presumed to leak along the field lines from the top of the cloud to the surrounding ionosphere. Note that field lines also go from the top of the cloud to ground thus leaking positive charge to ground. Negative charge is brought to ground mainly by lightning strokes and point discharge currents. The number of field lines between the cloud top and ionosphere compared to the number between cloud top and ground is an unanswered but crucial question which will determine the amount of charge supplied to the global fairweather circuit. For example, if the number of field lines going from the top of the cloud to earth would equal the number of field lines returning from earth to the bottom of the cloud, no current can flow to the ionosphere.

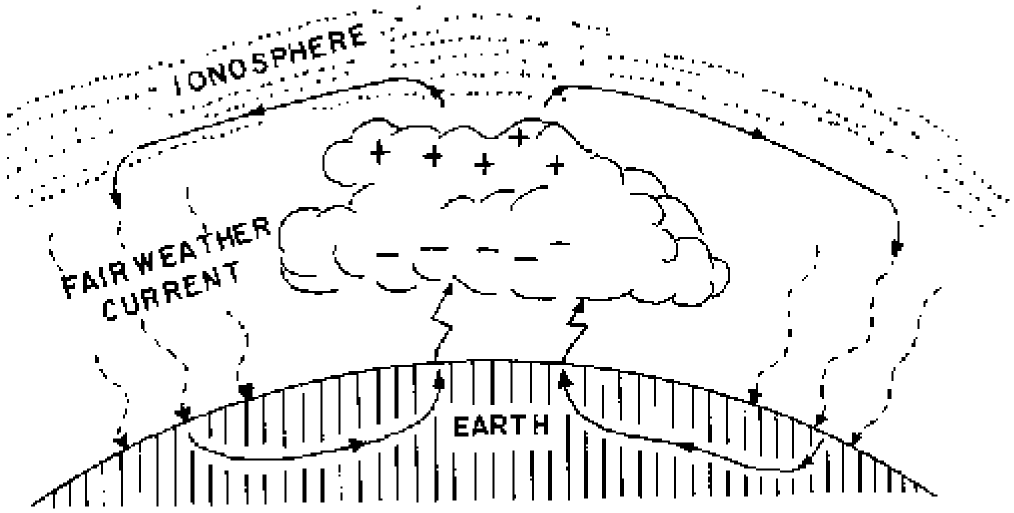

Fig. 17 The global electric circuit by C.T.R. Wilson.

Another problem presents itself when one examines the charge distribution of the fairweather field. Figs. 12 and 14 illustrate that about 90% of the fairweather field and charge is confined within an altitude of 2 km which is far below the conducting ionosphere. The situation is usually explained as follows: consider two conducting surfaces such as the ionosphere and the earth's surface carrying opposite charges at a potential difference of several hundred kilovolts, the earth's surface being negative and the ionosphere positive (see Fig 17). A current driven by thunderstorm generators is flowing in the form of negative ions towards the ionosphere and positive ions towards the earth's surface. Since conductivity and ion mobility increase with altitude, it is believed that negative ions (which flow upwards) will disappear faster on the positive electrode, the ionosphere, than positive ions can disappear on the earth's surface. Positive ions which face an increase in resistance are believed to slow down and congregate in a space charge cloud near the earth's surface. This is believed to produce an excess of positive ions near the earth's surface and could

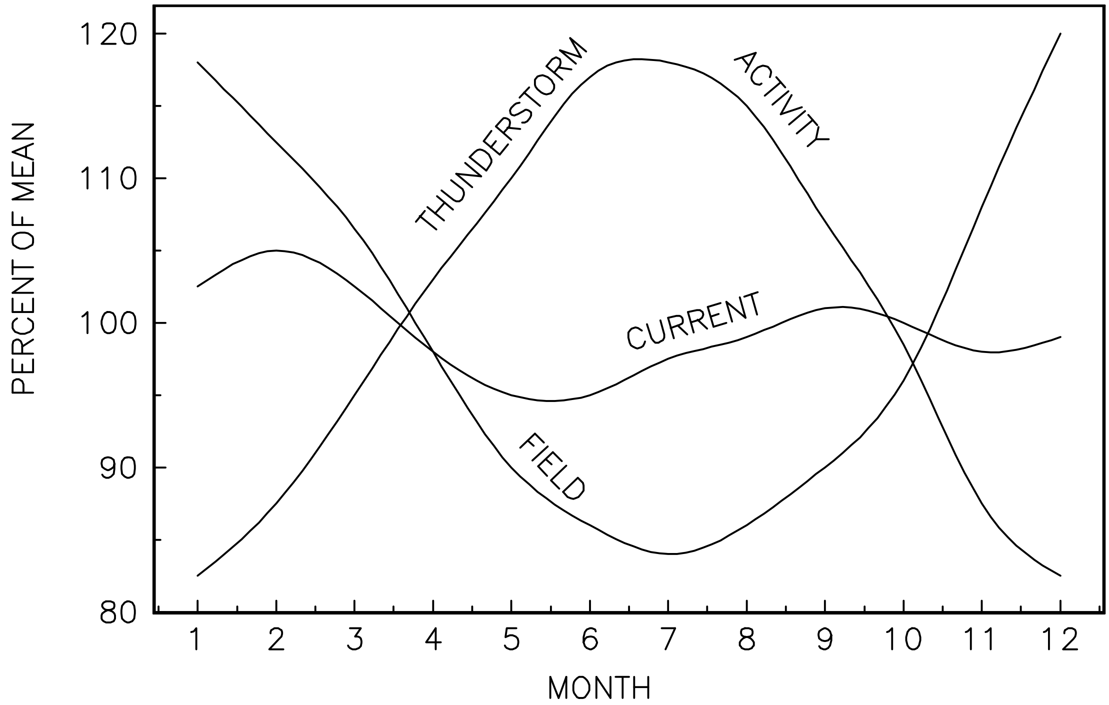

Fig. 18 Variation in fairweather field and current compared to thunderstorm activity.

explain the observed positive space charge distribution of the fairweather electric field. Plasma physics does not allow ions of one kind to disappear faster on one of the electrodes because it would mean that one of the electrodes or conductors in question would carry more current than the other, which is impossible. Theory and experiments require that an opposite and equal amount of space charge must build up near the other electrode as well (see Papoular 1965). In the case of the fairweather electric field, such a negative space charge near the ionosphere or near tops of thunderstorm generators, have never been found.

Data presented by Imyanitov and Chubarina (1967) provides little support for the closed circuit idea since they show that annual variations in the fairweather field are not in phase with typical thunderstorm activity throughout the world for the same period (see Fig. 18). Furthermore, Kasemir has pointed out that the curve showing diurnal variations of the fairweather field in Fig. 15 is much too smooth to fit the world-wide thunderstorm activity data, because recent satellite data show that thunderstorms are mainly active over continental land masses rather than over oceans (Turman, 1978, Turman and Edgar, 1982). The smooth curve in Fig. 15 might be more representative of the world-wide atmospheric convection and follows the field variations of the Austauch generator, a situation which would favour the electrochemical charging theory.

2.7.3 THE ELECTROCHEMICAL MECHANISM

The electrochemical charging mechanism considers the earth as an electrode immersed in a weak gaseous electrolyte, the naturally ionized atmosphere. The earth's surface will adsorb negative ions and achieve an electrode potential of about -0.25 volts which will appear at the earth-atmosphere interface in form of an electric double layer. This is analogous to a battery cell where an electrode becomes charged relative to an electrolyte. The thickness of the electric double layer is very small, about 1mm in the normally ionized atmosphere. The double layer can be pictured as containing field lines which connect each captured negative ion on the earth's surface with an excess positive ion left behind in the atmosphere. As convection and eddy diffusion lift the excess positive ions to higher elevations the field lines stretch thus increasing the potential with altitude. The result is an electric field build-up which will follow a pattern completely dictated by the mixing and diffusion mechanisms in the atmosphere such as shown in Figs. 12 and 13. The field strength at the earth's surface will equal the electrochemical potential divided by the double layer thickness $(0.25\ \text{volts}/\text{mm} = 250\ V/\text{m})$ which is in close agreement with measurements. With a few exceptions (Griffiths and Vonnegut (1975), Moore and Vonnegut (1977) and Willet (1980)) no serious criticism has yet been directed against the electrochemical charging mechanism perhaps because it is relatively new theory. The above investigators believe that contact potentials rather than electrochemical potentials are responsible for the results reported by the author and that such a charging mechanism is too insignificant to play any major part in atmospheric electricity.

CHAPTER 3

CHARGING MECHANISMS

3.1 SUMMARY

There are several basic charging processes proposed which in one way or another might contribute to atmospheric electric phenomena. Some of the more important are contact electrification, electrochemical charging, influence charging, diffusion charging and mechanisms involving freezing and splinting of ice particles. Most of the above charging mechanisms were devised to explain the charging of thunder clouds. Some theories, such as those involving influence charging for example, will not operate in the earlier stages of cloud growth, and others, which involve freezing and ice, cannot be considered dominating since warm tropical thunderstorms exist which do not contain ice. There are numerous other theories which will not be mentioned here and there are even theories which argue that a combination of all charging mechanisms might be at play at one and the same time. The situation is very challenging. The latest theory to be proposed is that of the electrochemical process put forward by the author. The electrochemical charging mechanism has the advantage of being able to explain both thunderstorm charging and fairweather electricity. So far it is the only charging mechanism that can be readily demonstrated by working laboratory models. Contact electrification involves mechanical contact between solids where electrons from a lower work function material spill over to a higher work function material. Contact potentials are of the order of a few tenths of a volt and might occur in the atmosphere when solid precipitation particles of different temperatures collide or when solid precipitation particles bounce off material surfaces either on the ground or in the atmosphere.

Any process in which charge is captured or transferred by ions is by definition an electrochemical process. Charge transfer by ions can be referred to as oxidation-reduction reactions. An ion which gains an electron is reduced and an ion that loses an electron is oxidized. Electrochemical potentials are encountered in everyday life and can be found in batteries and dry cells for example, and has been known to chemists and included in their text books for centuries. One problem, however, is that the language and conventions used by chemists are not exactly tailor-made for physicists who therefore, in the author's opinion, seem to shun the electrochemical effect and often confuse it with contact electrification. An attempt will be made later to explain the difference between contact potentials and electrochemical potentials as seen by a non-chemist.

Influence charging deals with charges that appear on material surfaces which are exposed to an electric field. For example, dust resting on the earth's surface will be negatively charged during normal fairweather conditions since the electric field lines from the positive space charge in the atmosphere above must terminate on the negatively charged earth's surface (the surface in this example being covered with dust). During strong winds the negative charged dust particles can become airborne and form highly electrified dust clouds. Dust and sandstorms are most often found to be negatively charged. The same explanation can be applied to waterfall electricity where the negative charge, induced by the fairweather field on a surface of water, is being carried over the edge of a waterfall. As the electrified water falls over the edge it breaks up into small drops and forms a mist of negative space charge, referred to as the Lenard effect or waterfall electricity, first discovered by Tralles of Bern in 1786. Induction charging in thunder clouds has been considered by several investigators and is based on the idea that cloud drops, which are polarized while subject to the electric fairweather field, preferentially capture negative charge from smaller drops. As large drops fall and collide with smaller drops a transfer of charge is believed to occur where the upper half or negative pole of a smaller drop gives up its charge during the encounter. Negative charge collected in this manner would descend and occupy the lower portion of a cloud while the smaller drops with excess positive charge would remain behind to form an upper positive region.

3.2 CONTACT CHARGING

There are many excellent books and papers on contact potentials or Volta potentials, such as Loeb (1958) and Lord Kelvin's famous paper presented at the Bakerian lecture to the Royal Society (1898). But ever since Voltas original observations there has been confusion between contact potentials and electrochemical potentials, a situation which persists even today. For example, Lord Kelvin became very upset when Professor Lodge presented his paper "On the Seat of the Electromotive Force in a Voltaic Cell" (1885) and later in a private letter to Lord Kelvin he expressed his belief that contact potentials are related to the difference in oxidation energies of different materials. Loeb in his book warns, "Volta potentials must never be confused with electrolytic potentials". With due respect to both Kelvin and Loeb (the latter was a colleague of the author's) the author believes that Professor Lodge was also right.

Kelvin's condenser system which is shown in Fig. 19 demonstrates how volta or contact potentials are measured. It consists of two large capacitor plates made of dissimilar metals (copper and zinc) which are separated by an adjustable air gap. A switch and an electrometer are connected in parallel with the capacitor plates. The plates are connected to an electrometer. At first the switch k is momentarily closed which will allow electrons to flow from the zinc plate to the copper plate because zinc has a lower work function than copper. An electric field with a total potential of V_c, which is the difference in work function between the two metals, will appear between the two surfaces. When the spacing between the plates is increased from a to b the field lines will extend and the potential across the electrometer will increase to $V = V_c(a+b)/a$. In the above example the effects of fringing fields and stray capacitance were neglected. The diagram in Fig. 20 illustrates the relationship between work functions and contact potentials. Fig. 20a shows a typical potential well diagram for a metal

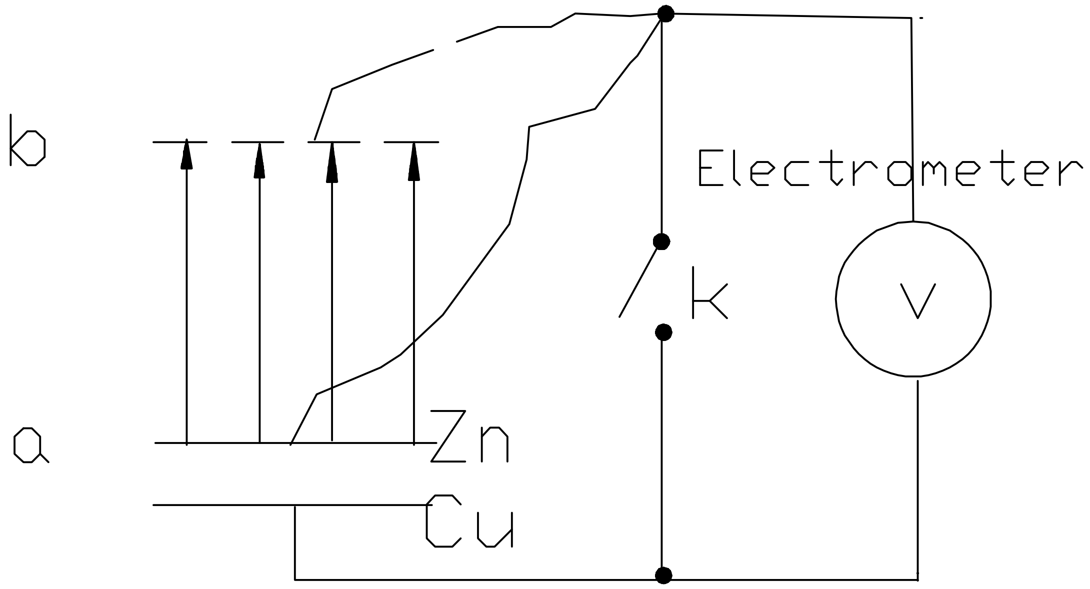

Fig. 19 Lord Kelvin's condenser system.

surface where the conduction and valence electrons are trapped at an energy level which is equal to the work function of the material in question. The potential barrier set up by the work function is represented in Figs. 20b and 20c by small electric cells between the conduction band of the material and its outermost surface. At first, before the switch k has been closed, there is no field between the zinc and copper surfaces. On closing the switch electrons will spill over from the zinc, having the lower workfunction to the

higher or deeper potential well of the copper. Bringing the conduction bands of both materials in electric contact will cause the difference in work function potential to appear across the gap of the plates. The amount of charge transferred is $V_c C$, where C is the capacitance of the plates. One characteristic feature of contact charging is that the current ceases as soon as the capacitance C is fully charged; i.e. contact potentials are not current driving sources such as galvanic cells, for example. The total amount of energy dissipated in the contact charging process is

$$W = \tfrac{1}{2}V^2C \tag{3}$$

It is interesting to note that in his lecture to the Royal Society, Kelvin mentioned one experiment in which he placed a drop of cold water between the plates in his condenser apparatus and found the electrometer swing toward the opposite direction to that of the contact potential, but with the same magnitude. He attributed this effect to electrolytical conduction and not to contact potential charging. Experiments by Maclean and Goto in Glasgow in 1890 proved that zinc and copper, with fumes from flames passing up between them, gave, when connected to an electrometer, deviations in the same direction, as if cold water had been in place of the flame. Kelvin also mentioned that beside the wonderful agency in fumes from flames, there were reports by other investigators that ultraviolet light and x-rays traversing the gap between the plates caused the same effect as that of cold water. These effects, Kelvin thought, would to some degree fulfill Professor Lodge's idea of some potentially oxidizing process, but, "each one fails wholly or partially to maintain electric force or voltaic potential difference in the space between them". Further communication between Kelvin and Professor Lodge broke down when Lodge, in a letter, said that Kelvin was unrepentant.

Are contact potentials related to the chemical properties of the materials in question or are they purely a physical phenomenon? To clarify this problem one first needs to ask; where does the energy come from that causes contact potentials to build up? The contact potential which equals the difference in work function between two materials is also equal to the binding energy difference between the electrons in the materials. For example, the electrons in copper are more tightly bound to the atoms in the surface lattice than the electrons in zinc. Therefore, it will require more work to remove an electron from the copper surface than from the zinc surface, thus the name "work function". The chemical binding forces between the metal atoms can be pictured as hooks bonding the atoms together in all directions. However, at the surface there will be dangling bonds because the outermost atoms will have nothing to attach to outside the surface boundary. These dangling bonds make up for the surface energy or work function potentials which are simulated by the electric cells in Fig. 20 b and c. Since the energy of dangling bonds are chemical in nature then any transfer of charge, due to this energy, could technically be classified as an electrochemical process.

What will happen if the space between the plates in Fig 20c is filled with an equal amount of positive and negative ions either in form of a liquid or an ionized gas such as air? Will the negative ions go to the positive plate and the positive ions to the negative plate of the condenser and will there be a continuous current flowing in the circuit as long as the ion supply lasts? The answer is yes. But does the energy that drives the current in the circuit come from the contact potential (potential difference in work function between the materials)? The answer is no. First, the energy available from the contact potential is too minute (see Equation (3)) and cannot sustain a current for very long. It is therefore very clear that the energy driving the current must come from the ions themselves as they interact and recombine with the surfaces. Recombination here means the neutralization of an ion as it loses its charge to a material surface. The electric field between the plates, set up by the contact potential, see Fig. 21a, will draw negative ions to the zinc and positive ions to the copper. Once negative ions enter the zinc, charge is brought to the surface in the form of electrons.

These new electrons will immediately spill over from the zinc to the deeper potential well of the copper work function. However, no constant current can flow unless other electrons are allowed to leave the copper electrode at the same rate new electrons spill over from the zinc; i.e. the rate of negative charge brought to the zinc by negative ions must equal the rate of negative charge leaving the copper to combine with the positive ions drawn to the copper plate.

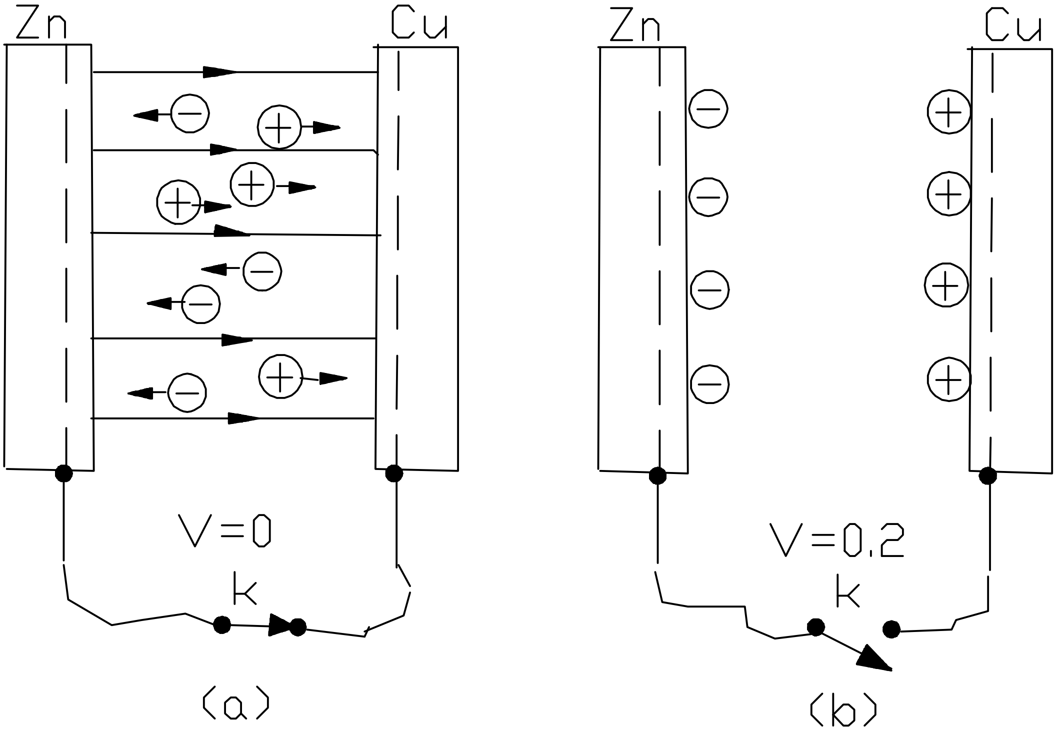

Fig. 21 Contact potentials in an ionized environment. (a) Ion current with switch k closed. (b) Potential build-up with switch k open.

What is the source of energy that is capable of lifting the electrons back out of the potential well of the copper work function? It is obviously not the work function or contact potential itself because that would be analogous to lifting oneself by the hair. The energy supplied must come from the ions residing in the spacing between the plates. The ionization or recombination energies of the ions will provide the necessary energy and a current will flow as long as the supply of ions lasts unless switch k in Fig. 21a is opened. If the current is interrupted by the switch, ions will continue to flow and charge the electrodes until a back-emf is built up that cancels the original field of the contact potential across the plates, at which point the flow of ions ceases. A potential equal to the contact potential will now appear across the switch and a situation such as shown in Fig. 21b will be reached.

The presence of ions between two electrodes of dissimilar materials and their ability to generate a steady current is nothing less than a galvanic cell. The primary source of energy is the ionization agency which might be radioactivity or cosmic rays as in the case of our ionized atmosphere. Ions are also produced in liquids where one or both electrode materials might slowly go into solution in the form of ions. The dissolved ions supply the energy that drives galvanic currents through circuits and usually at the cost of the lower work function material itself. A typical example is the flashlight battery or dry cell. Most charging processes involving ions are electrochemical processes.

3.3 ELECTROCHEMICAL CHARGING

Electrochemistry has played a major part in both industry and science for the last two hundred years. It might come as a surprise, however, to discover that the function of the familiar dry cell, such as used in portable radios, is not yet perfectly understood. The chemical reactions taking place are believed to be as follows: zinc metal from the outside casing is dissolved by the acidic electrolyte and leaves the container wall as positive metal ions. The charge removed by the positive ions going into the solution will cause a back- emf to build up between the zinc and electrolyte. When the back-emf has reached the same value as the solvation energy, the process stops because the electric field of the back-emf will prevent more ions from going into the solution. The result is an electric half cell with the positive metal ions in the solution forming a tightly bound electric double layer with the negative charged zinc. The other half of the cell is the carbon rod which has the function of supplying electrons to the electrolyte during operation but, the exact chemical reaction involved is not known. The voltage of the cell is determined by the difference in potential between the two half cells. The absolute energy or voltage of each half reaction is not known and no method has yet been devised to measure half cell potentials separately. The problem is how to electrically connect a voltmeter across the double layer without introducing another half cell reaction. Chemists have therefore settled for a compromise method whereby all types of half cells are compared to the voltage produced by a standard cell, the hydrogen half cell. This arbitrary method considers the potential of the hydrogen half cell as equal to zero and the difference in potential between the hydrogen half cell and any other half cell can be found in tables under the heading of Electromotive Force Series. One difficulty is that the potentials listed in the Electromotive Force Series refer to electrodes which are immersed in their own individual solutions containing their own ions, whereas in the dry cell both electrodes are in the same solution; i.e. a solution which contains zinc ions but no carbon ions. Another important question is what part does contact potential play in the electrochemical cell? The contact potential is often equal to or very near the potential of the cell itself and contact potentials are hardly ever mentioned in electrochemistry. Are electrochemical and contact potentials so closely related that when Professor Lodge argued with Lord Kelvin 100 years ago, he was right stating that they are of the same nature? It is now known for certain that the valence electrons, which determine the magnitude of contact potentials in metals, also determine the energy involved in electrochemical reactions.

In order to understand the electrochemical charging mechanism, especially as applied to atmospheric electricity, it might be helpful to describe a few laboratory and field experiments which were carried out in an attempt to clarify some of the above problems. Consider the following tests, which can readily be performed in the laboratory, and which are shown in Figs 22 a and 22 b:

1. Lower into an empty glass beaker two electrodes of differing materials (e.g. gold and magnesium) and connect an electrometer across the two electrodes. When a suitable radio-active source (e.g. Po 210, 500μCu) is placed at the bottom of the beaker, a potential of 1.2 volts will be registered between the electrodes, magnesium being negative with respect to gold.

2. Remove the radioactive source and fill the beaker with sufficient water to partially immerse both electrodes. The electrometer will again register a potential of 1.2 volts and the same polarity.

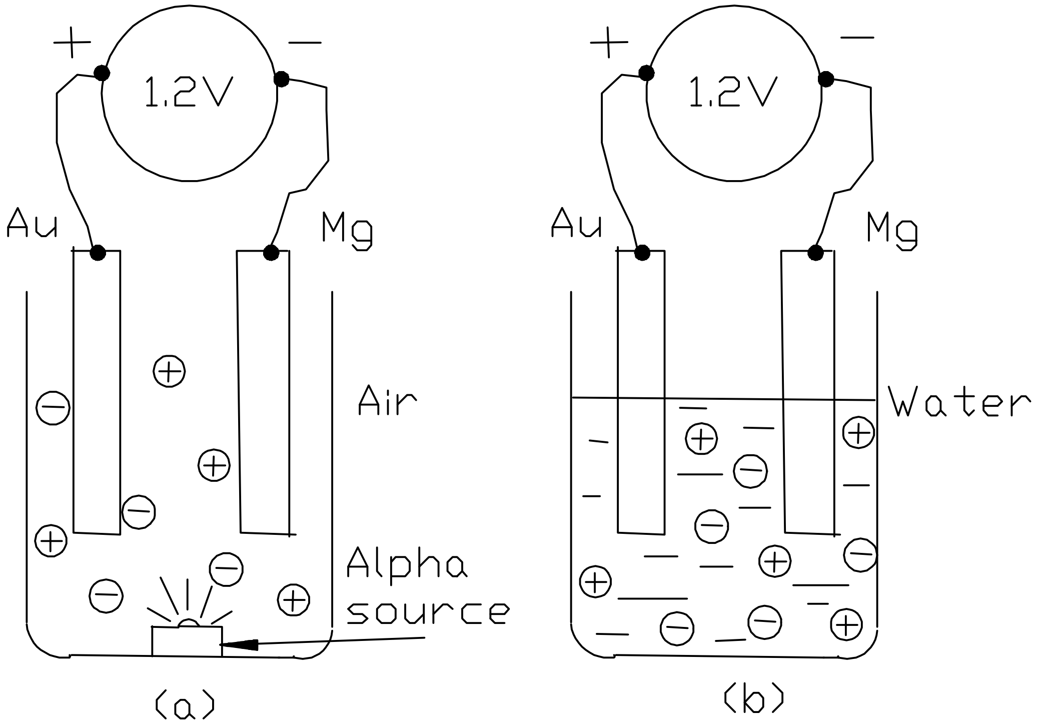

Fig. 22 Experiment demonstrating electrochemical charging. (a) Galvanic cell with ionized air as electrolyte. (b) Galvanic cell with water as electrolyte.

Both experiments deal with an electrochemical cell, using water for electrolyte in one case and air in the other. The fact that water contains ion pairs makes it an electrically conducting electrolyte which is vital for an electrochemical cell. In the first case, Fig. 22a, the beaker contains air instead of water, but the air is slightly ionized by the radioactive source, and although the number of ion pairs is relatively low, the ionized air is electrically conducting and exhibits the same properties characteristic of an electrolyte.

The average number of ions in the atmosphere is of the order of one billion pairs per cubic metre. The atmosphere is thus very much like an electrolyte. Its ion pairs are produced mainly by the constant bombardment of cosmic rays that reach our atmosphere from solar and stellar sources. Other ions are produced by radiation from radioactive materials in the atmosphere and in the earth's crust (see section 2.1.).

That material surfaces in contact with the ionized atmosphere are subject to electrochemical charging can also be shown by simply probing the atmosphere with electrodes and it can be easily demonstrated that in the absence of external electric fields negative ions rather than positive ions have a tendency to adhere to material surfaces. It can also be observed that when the probes are ventilated by strong winds, more ions are supplied and the negative ion current to the probes increases accordingly. At first, when such measurements were performed it was not at all clear what caused this type of charging although it was believed at the time that work function potentials might play an important part in the charging process. Experiments were therefore set up in the laboratory in an attempt to duplicate the field measurements described. Surfaces of diverse materials were ventilated by artificially ionized air. The results revealed a marked difference in activity among various materials in contact with the ionized air. For example, a small sheet of magnesium metal will absorb negative ions and continue to charge until it reaches a potential of -1.6 volts with respect to its surroundings. Each material tested was found to reach its own characteristic potential. An abridged list of these materials with their potentials appears in Table 1. The potentials in Table 1 agree with the potentials measured by the Gerdien cylinder shown in Fig. 11 section 2.1.

Material	Work function	Equilibrium Potential Volts
Magnesium	3.66	-1.6
Wet Filter Paper	-	-1.05
Aluminium	4.24	-1.0
Cadmium	4.22	-1.0
Tantalum	4.25	-0.65
Molybdenum	4.50	-0.6
Copper	4.65	-0.45
Stainless Steel	4.75	-0.4
Ice	-	-0.4
Gold	5.35	-0.22

Table 1. Work function and electrochemical equilibrium potentials for different materials.

At first it was disappointing to discover that the potentials in Table 1 were not at all proportional but rather inversely proportional to the work function potentials of the different materials in question. However, Table 1 has a very familiar appearance to the chemist; it resembles a chemical activity series in which the electrical potentials are values related to the oxidation energies of the materials in question. To further prove the electrochemical effect, the same materials were immersed in distilled water, two at a time. Differences of potential between the two materials were then measured and found to be directly proportional to the respective differences between their values in Table 1. From the experiments and the results of Table 1 it became clear that we were dealing with an electrochemical effect and the following conclusions were drawn: negative ions in air are formed from acidic molecules such as O_2 and NO_2. These molecules are electrophilic (electron seekers) and capture free electrons produced in air by the various ionization processes. The molecular ion, with its valence slightly reduced by a captured electron, still remains acidic and very active as an oxidizer. When the molecular ion with its piggy back electron oxidizes a surface material, negative charge is transferred by the captured electron to the surface. As more ions reach the surface, a negative back-emf will build up, eventually repelling any incoming ions until no more can reach the surface. Just as in the case of the dry cell an electrical equilibrium potential is achieved. The electrochemical reaction halts when the back-emf has reached a value equal to the oxidation potential, or the energy of the chemical oxidation-reduction reaction involved. Oxidation- reduction reactions can be described as follows: if two elements combine where one wants to share one or more of its electrons with another element which is an electron acceptor, then an oxidation-reduction reaction has taken place. The electron donor is said to be oxidized and the electron acceptor is reduced. It is interesting to note that in Table 1 the elements on top of the activity list are the elements with the lowest work functions. These elements freely share their valence electrons and become easily oxidized because of their lower electron binding energies or lower work functions. Electronegative elements or compounds are the electron seeking oxidizers that want to react with and oxidize material surfaces. The oxidizers or electron seekers appear most commonly as negative ions in the atmosphere and solutions because of their tendency to pick up free electrons in the surrounding environment. When the oxidizer reacts with a material surface it brings a captured electron along. The electron will charge the surface and the chemical reaction can therefore be classified as an electrochemical reaction.

The fact that oxidizers in general appear as negative ions forms the basis for electrochemistry in the atmosphere and in solutions. It is very important to remember, especially in the case of atmospheric electrochemistry, that the process which brings the negative ion to a material surface is the chemical reaction and not the electric field of the ionic charge itself. In an electrochemical reaction the electron simply enjoys a piggy-back ride to the surface and the image force produced by its charge is too feeble and short in range to compete with chemical processes. Also, the strength of the image forces are equal for both positive and negative ions so that no preferential charging of either sign can be expected. Nevertheless, a theory put forward by Phillips and Gunn (1954) considers the difference in mobility between negative and positive ions as possible mechanism for preferential charging. This theory will be discussed in section 3.4.

Numerous experiments in ionized air revealed that all metals and conductors tested proved to be oxidized by negative ions and achieved negative equilibrium potentials. No positive equilibrium potentials were ever encountered. In cases where two electrodes are immersed in an ionized medium, both electrodes become negatively charged relative to the electrolyte, the lower work function material being more negative. The potential between the electrodes equals the difference in oxidation potentials between the materials which also seems to equal their difference in work function except for the reversal of sign. The results were the same for electrodes immersed in ionic solutions where the electrodes did not go into solution. No tests were performed involving solvation energies.

One striking feature of the electrochemical charging process is the formation of the electric double layer. The oxidiation potential and the thickness of the double layer determines the charge density on the oxidized surface. In normally ionized air the double layer thickness is about 1 mm which means that a surface of water, for example, which has an oxidation potential of -0.25 volts, will charge to

$$Q / \mathrm{m}^2 = V_0 \varepsilon_0 / d \tag{4}$$

where d is the double layer thickness and V_0 the oxidation potential. The value of d was derived from laboratory experiments which proved that the average thickness of the double-layer in air, to the accuracy of the measurements, is equal to the average distance between the ions. It appears that each time a negative ion reaches the surface, it leaves behind a positive ion at a distance equalling the average ion spacing. This distance for normally ionized atmosphere is about one millimetre. In an experiment that followed, isolated spheres (to simulate cloud drops) were ventilated by ionized air for the purpose of studying the charge collection on their surfaces. Negative ions reacting with the surface of a drop or a sphere leave behind positive ions in the surrounding air, thus building up a diffuse space-charge cloud around the sphere. This cloud of positive ions forms an electric double-layer with the charged surface of the sphere. The double-layer, formed by the charged surface of a sphere surrounded by its diffusion cloud of opposite charge, constitutes a spherical capacitor with a capacitance of

$$C = 4\pi\varepsilon_0 R(1 + R / d) \tag{5}$$

R is the radius of the sphere, and d is the mean thickness of the double-layer. The charge on the sphere can then be calculated from the electrostatic expression

$$Q = V_0 C = V_0 4\pi\varepsilon_0 R(1 + R / d) \tag{6}$$

where the double-layer voltage, V_0, is also the oxidation- reduction potential of the reaction between the ions and material in question. The sphere with its attached double- layer is, of course, electrically neutral with regard to its surroundings. No drastic charge separation has yet occurred.

The fact that the sphere or drop is ventilated (by falling through the atmosphere for example) is of the utmost importance because the flow of air will partially strip away and remove the outer positive layer of the double-layer, a process that not only increases the potential of the sphere but also makes it appear to be negatively charged relative to its general surroundings. For example, removing the outer-charged layer to infinity will increase the potential on the sphere to

$$V = \frac{Q}{C} = V_0(1 + R/d) \tag{7}$$

Common experimental values for charged water drops are shown in Figure 23. These values were obtained from actual measurements in the atmosphere by several investigators and are compared here to the predicted values represented by the solid curve. The curve is constructed from Equation (6), using a double-layer thickness of one millimetre, a distance that equals average ion spacing in the normally ionized atmosphere. An oxidation potential of $V_0 = -0.26$ volts for water was chosen from the experimental results of Chalmers and Pasquill (1937) who, in their laboratory, measured the equilibrium potentials on water drops. The oxidation potential for water in Table 1 is -0.4 volts

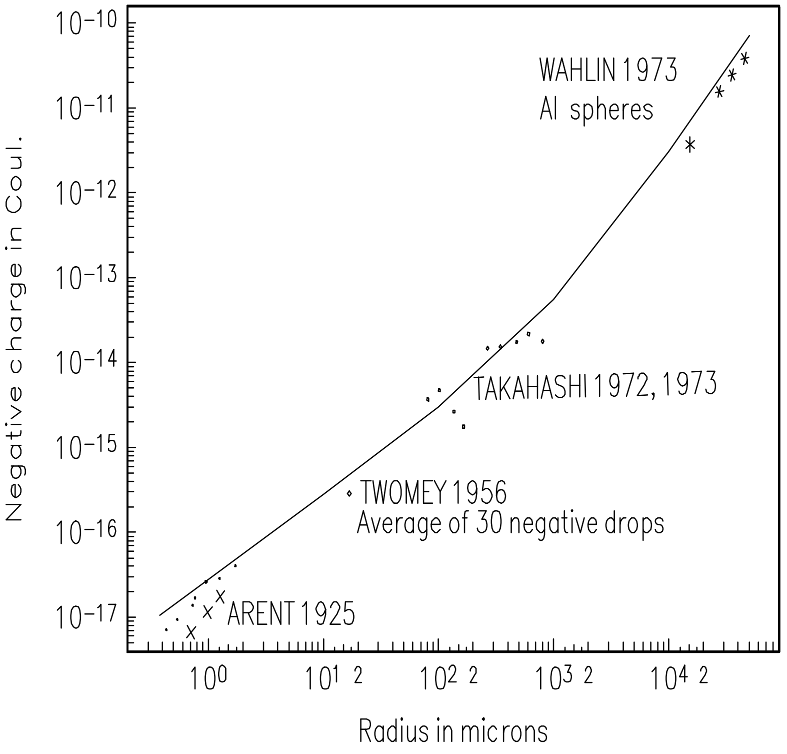

Fig. 23 Charge-size measurements of rain drops compared to values predicted by the electrochemical charging process.

which is the value obtained for water when ventilated by an equal amount of positive and negative ions. In the normally ionized atmosphere there are more positive than negative ions. A typical ratio is $N^+ / N^- = 1.2$ which will lower the equilibrium potential to about one third (see the results in Fig. 11) and which agrees with Chalmers and Pasquill's results.

3.4.1 OTHER CHARGING PROCESSES

Except for the well established effects of contact and electrochemical potentials there have been several other charging mechanisms proposed in order to explain atmospheric electric phenomena. Some involve influence charging in combination with colliding drops such as the Elster-Geitel theory, or influence charging and the capture of ions as proposed by Wilson. There are charging mechanisms which consider ice splintering and freezing of water drops to be important in producing charge on precipitation in clouds. The process of evaporation and recondensation of water has intrigued many investigators, including Volta, as a possible source of positive and negative charge in clouds. Takahashi (1973) has recently carried out work along these lines. The validity of the above charging mechanisms are difficult to verify since they lack rigid experimental proof. Recent years have seen many sophisticated computer models which will work if the right parameters are plugged in. This is especially true for influence charging mechanisms involving collision between polarized drops in strong vertical electric fields. Some mathematical computer models are often conceptually difficult. Since mathematics is only a tool of science it is more desirable to have a conceptual theory that is mathematical sound than a mathematical theory that is not conceptually sensible.

3.4.2 THE ELSTER-GEITEL PROCESS

The Elster-Geitel (1885) process deals only with the charging of precipitation particles such as drops in clouds. It is based on the assumption that cloud drops, which are polarized in the electric fairweather field, collide with each other and exchange surface charges in a manner that will enhance the fairweather field to a magnitude found in thunderstorms. The proposed charging mechanism is shown in Fig. 24 where a smaller drop which is still light enough to be swept upwards by the updraft winds in the cloud, collides with a much larger and heavier drop falling down through the cloud. Since the large drop is polarized in the electric fairweather field its upper surfaces will attain a small excess of negative charge while the same amount of positive charge will appear on the lower surface. A small drop bouncing off the lower surface will pick up some of the positive charge at the moment of contact, and bring it along to the top of the cloud while the heavier and larger drop, now negative from the loss of positive charge, will continue to fall and bring negative charge to the lower region of the cloud. It can easily be seen that as

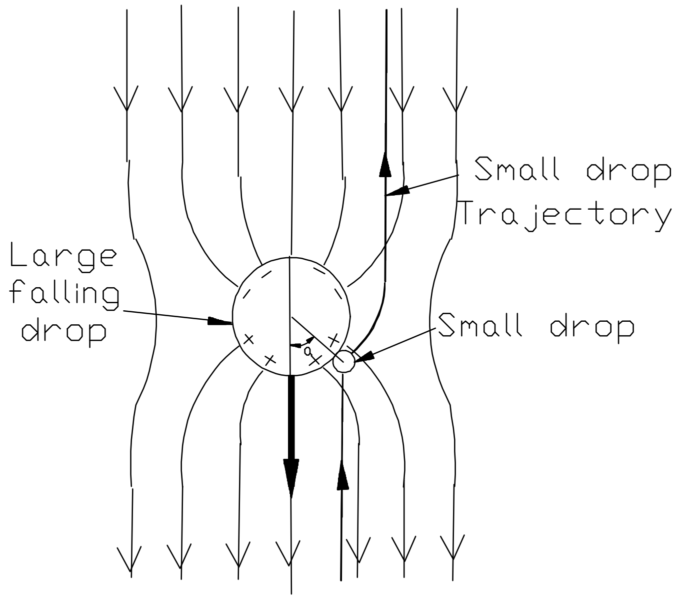

Fig. 24 The Elster-Geitel charging process of cloud drops.

charge is being separated the electric field strength will increase which in turn intensifies the charging process.

Although sophisticated computer models of the Elster-Geitel theory have been studied (Sartor (1954), Levin (1975) and (1983)) the general feeling is that the charging mechanism is too weak. The theory might possibly work if the initial electric field strength was equal to that found in thunderstorms in which case some other process must prevail (Pathak 1980). Unfortunately there is no laboratory support for the Elster-Geitel theory and some of the unanswered questions are: do small drops really bounce off larger drops at a reasonable rate or do they simply coalesce? How important is the grazing angle of the impact?

3.4.3 THE WILSON EFFECT

The Wilson (1929) effect is similar to the Elster-Geitel process with the exception that instead of small drops colliding with larger polarized drops negative ions are believed to be swept up by the larger drops as they fall through the normally ionized air. The positive charge induced on the bottom half of a large drop is believed to preferentially collect negative ions as the drop falls down to lower altitudes thus leaving an excess positive charge behind at higher levels. One serious objection to the Wilson theory is that there are not enough ions produced inside a thunder cloud to account for the amount of charge separated.

3.4.4 DIFFUSION CHARGING

Gunn (1957) considered a charging mechanism which is based on the difference in mobility between positive and negative ions. He assumed that since negative ions display a higher mobility in an electric field than do positive ions they must be less massive and therefore also have a greater diffusion coefficient in the absence of electric fields.

The expected result is that negative ions will diffuse on to cloud drops at a higher rate than positive ions can. Cloud drops will therefore become more negatively charged and as they fall down to the lower region of the cloud they leave an excess of positive charge behind in the upper region. Experiments with metal spheres ventilated by ionized air were carried out by Phillips and Gunn (1954), see Fig. 25. They confirmed that chrome plated metal spheres exposed to ionized air indeed charged negatively and reach certain equilibrium potentials.

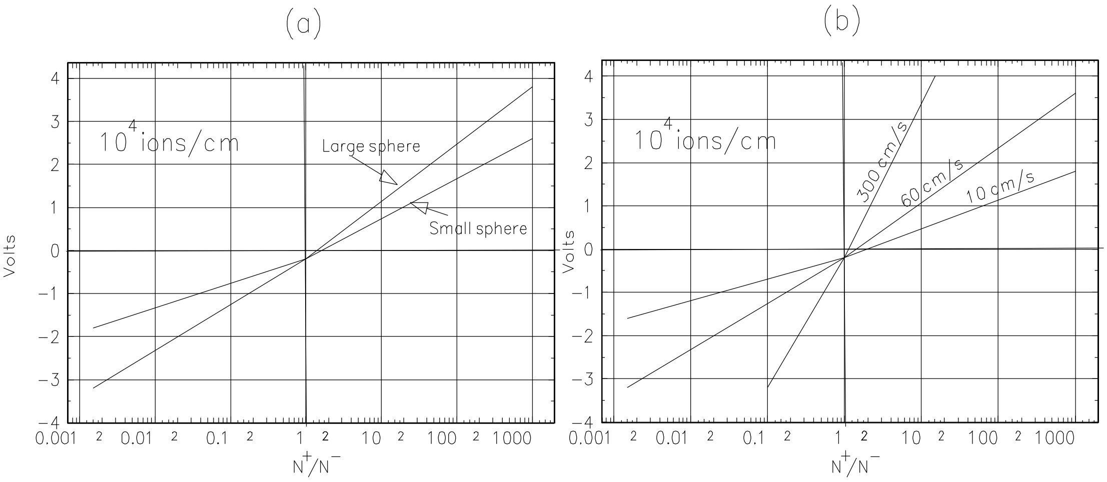

Fig. 25 Phillip's and Gunn's Experiment with metal spheres. (a) Equilibrium potentials for different dia. spheres. (b) Equilibrium potentials for different air velocities.

What is interesting about Phillips' and Gunn's experiment is its similarity to the experiments which demonstrate the electrochemical charging mechanism by the use of Gerdien cylinders, see Figs. 10 and 11. In fact, some investigators argue that the equilibrium potentials in Table 1 and the results shown in Figs. 10 and 11 can be explained by the diffusion theory. But this is hard to believe since the diffusion theory does not predict that different materials charge to different equilibrium potentials as shown in Table 1. Also, the energy of the diffusion process relates to the thermal agitation of the ions in their atmospheric environment and is determined by the air temperature. This means that the equilibrium potential, using Boltzmann's constant k and a maximum air temperature of T = 20 C, cannot exceed

$\frac{3}{2}kT \times 0.25$ or 0.008 volts where 0.25 represents the 25 percent higher mobility of negative ions over positive ions. This is only 3% of the values shown in Table 1 and the graphs of Phillips and Gunn (Fig. 25).

3.4.5 FREEZING POTENTIALS

Although it is known that warm clouds (clouds that do not contain ice or frozen precipitation) can charge to considerable potentials and occasionally produce lightning, there is still a great deal of attention devoted to charging processes that might involve icing. One reason for this is the observation by Simpson and Scrase (1937) who noticed that separation of charge in thunderclouds seems to occur in regions where the temperature is below freezing. They thought that colliding ice particles might charge negatively and leave positive charge behind in the air in the form of positive ions. The idea was further developed by Reynolds (1954). Workman and Reynolds (1950, 1953) have also discussed a theory in which glazing processes were assumed to produce charge. Many theories have been put forward which involve freezing of water, but again there are, unfortunately, no convincing laboratory experiments.

CHAPTER 4

THE THUNDERCLOUD

4.1 THERMAL DYNAMICS

On a warm and sunny day heat is absorbed by the earth's surface causing both water vapour and hot air to rise to higher atmospheric levels. The warmer the air the more water vapour it can hold before saturation. The secret of a thunderstorm and its devastating power lies in the amount of water vapour present. The latent energy of water vapour is the key factor in thunderstorm formation and electrification. At the beach most of us have experienced the sensation of cold after getting out of the water. The explanation is that water takes away heat from the body surface at a rate of about 540 calories or 2250 joules per gramme when it evaporates. When water condenses to form drops, the same amount of energy, in the form of heat, is released. When a cloud is formed by warm humid air reaching higher and cooler levels, condensation will create small drops between 5 - 10 microns dia. During condensation latent heat is released warming the surrounding air which will rise further (the hot air balloon effect) to considerable heights pulling more humid air up from below to take its place. A chain reaction starts when humid air is fed in from below pumping more and more energy into the cloud in the form of heat and convection. A cloud might grow up to 60,000 feet or 20 km in height in very narrow columns. Updraft velocities can easily reach 30 m/s. Each column is called a cell and a thundercloud usually consists of several cells. Each cell has an average life time of 30 minutes. When a cell reaches a maximum altitude it is in a so-called mature stage, at which time the cloud top usually flattens out to form the typical anvil shape often associated with thunder heads. The flat top is believed to occur when a cloud reaches the stratosphere or the boundary in the atmosphere where air temperatures begin to rise with altitude which will cause the cloud to evaporate again. In the growing stage of a cloud, drops increase in size as they reach higher levels and eventually become heavy enough to overcome the updraft velocities of the convection. At this point rain or precipitation starts to fall down and the cell has reached its dissipating stage. At greater latitudes, thundercloud precipitation without exception always reach temperatures below freezing. Hail and sleet are formed which often fall down and reach ground before melting. The cold precipitation will cool the air in the cell which becomes heavy and begins to move downward as well. The cold heavy air might cause considerable down drafts which, when reaching ground, supply the outward rush of cool air often felt as a relief to most of us after a hot day. When precipitation and down drafts occur the cell is said to be in its dissipating state and although some lightning activity is still going on its life is nearly over. New cells are formed adjacent to the old ones and often while observing their growth one can see small bubbles or turrets developing above and around each cell. The thunder cloud described is a typical heat cloud or isolated storm. Also common are lines of thunderstorms or squall lines. Lines of thunderstorms are formed when a cold front wedges in under the warm humid air mass along a warm front and squall lines can extend for several hundred miles. The energy source is the same, namely condensation of water and release of latent energy. Thunderstorms along a squall line often seem to lean over on their sides because of the heavier and cooler air wedging in underneath the warm front. Although there is considerable entrainment of air through the sides of such storms, the main energy is still being supplied by the updraft winds caused by condensation and convection.

4.2 THE ENERGY OF THUNDERSTORMS

The energy of a thunderstorm is determined by the amount of water vapour present. Typically, a single cell contains 8×10^{8} kg of water (Israel 1973) of which about 60% is converted into heat and precipitation. The total energy dissipated by a cell is therefore 1.4×10^{14} joules per cell. If the average life time of a cell is 30 minutes then the average power per cell equals 7.8×10^{10} watts. Since it is estimated that about 2,000 thunderstorms are active at the same time around the earth then the total energy dissipated must equal about 1.6×10^{14} watts which is about 0.1% of the energy reaching the earth's surface from the sun.

4.3 THE ELECTRICAL ENERGY IN THUNDERSTORMS

The electric energy of a thunderstorm can be determined in several ways. Schonland (1950, 1953) for example, estimated the potential difference involved in a typical lightning flash to be about 10^{8} and 10^{9} volts while the average charge transferred is about 20 coul. The total amount of free charge separated in a thundercloud is about 1400 coul according to Wormell (1953). From the above information we can determine the total electric energy involved to be of the order of $\frac{1}{2}VQ = 7 \times 10^{11}$ joules. A more realistic method presented by Israel (1973) yields a larger value of 1.7×10^{13} joules. In Israel's approach the average thunderstorm cell is compared to an electric circuit diagram (Kasemir 1965) such as shown in Fig. 26. According to Wait (1950), on the other hand, a thunderstorm cell generates on the average 2.5 amperes of current and from Ohm's law one then finds that the total power output of a cell is $RI^{2} = 9.4 \times 10^{9}$ watts, which when integrated over the duration of a cell (30 min.) amounts to 1.7×10^{13} joules.

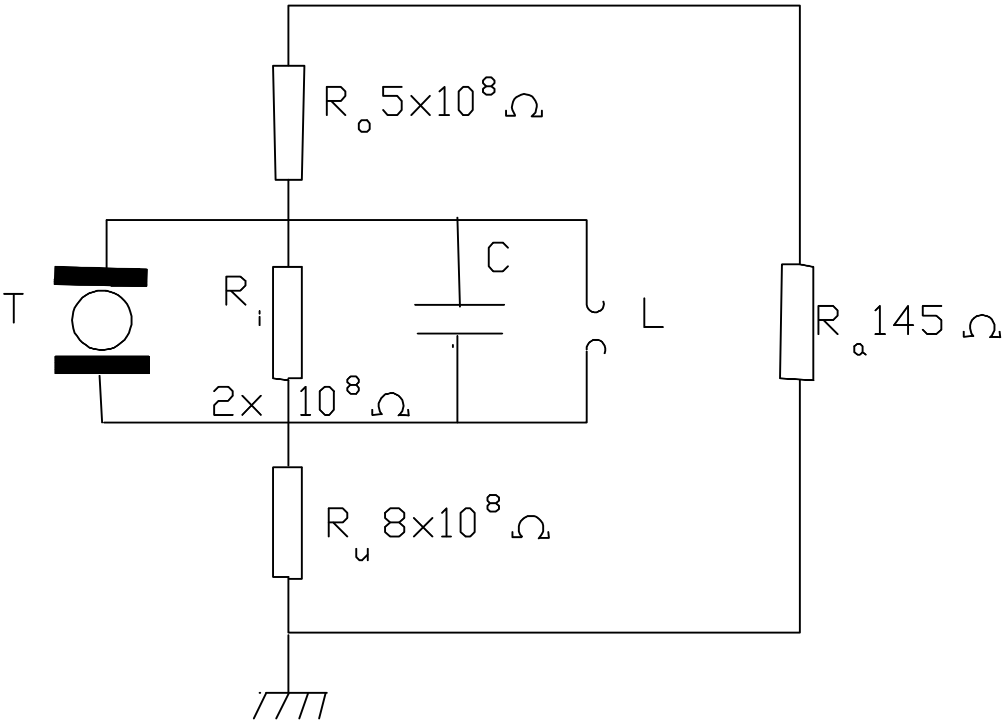

Fig. 26 Electric circuit diagram of a thunderstorm (Kasemir).

There is at least one serious objection to the use of Ohm's law in determining the electric power of a thunderstorm. There is no doubt that the internal resistance of a thundercloud, such as represented in Fig. 26, is an accurate measurement since it has been determined in situ by conductivity measurements. The problem is that the conductivity or resistance depends on the number of ions available in the cloud. Ions are the charge carriers in the cloud and solely responsible for the flow of electric current. Considering that the normal ion production in the atmosphere is about ten ion pairs or 1.6×10^{-18} coul of charge per cubic centimetre per second and that the average thunder cloud cell measures fifty cubic kilometres in volume, then the total charge production within the cell is only 0.08 coul per second which translates to a meagre saturation current of 80 mA.

Ohm's law will not hold once a state of saturation has been reached. An ohmic current of 2.5 amperes used by Israel might, therefore, not be a representative value. If the charging current in thunderstorms is non-ohmic the only other alternative is a mechanical transfer of charge by means of convection and updraft currents or by the process of gravitation in which charge is transported by falling precipitation particles. The author has reason to believe that when Israel calculated the average electric power involved in charging of clouds he not only considered the ohmic current but also took the mechanical currents into account.

An interesting thought is that if one could harness a lightning bolt there would be 100 kW hours of energy available, enough to keep a 100 watt light bulb burning for a month and a half. There are nearly 50,000 thunderstorms active around the world per day, and if each storm produced 100 lightning bolts, there would be close to 20,000 megawatts, which is only enough power to satisfy the needs of a large city such as New York.

4.4 THE LIGHTNING DISCHARGE

There are two types of lightning discharges, namely cloud to ground lightning and intracloud lightning or cloud to cloud discharges. As the reader recalls from section 1, Benjamin Franklin observed that thunderclouds tend to form gigantic electric dipoles in the atmosphere where the lower portion of the cloud is predominantly negative and the top positively charged. Occasionally a small pocket of positive charge can be found in the lower cloud section during the clouds dissipating stage in the vicinity of the precipitation shaft. There is about three times as many intracloud discharges as cloud to ground flashes, a ratio which seems to vary somewhat with geographical location. Normally negative charge is brought to ground by lightning that originates from the lower section of a cloud. However, as more and more negative charge is drained by successive lightning bolts to ground, the more the positive charge in the upper half of the dipole becomes dominant. The imbalance of the dipole will eventually cause a positive discharge to appear from the upper region of the cloud to ground. The ratio of positive to negative ground strokes is about 1 to 10 but a positive discharge from the upper region of the cloud is as a rule ten times more powerful and carries ten times more charge.

A lightning flash to ground might consist of several ground strokes which appear in such a rapid sequence not distinguishable to the naked eye but easily observable with the aid of a Boys camera (see Fig. 6). In fact, pictures taken with a Boys camera reveal quite a complicated discharge mechanism of lightning. It appears that lightning is triggered by faint pilot streamers (Schonland, 1938) which provide the initial ionized path from cloud to ground by weak corona discharges.

The pilot streamer is usually followed by a stepped leader which can be described as small current surges catching up with the pilot streamer in small steps averaging 50 metres in length. As the pilot streamer works its way down to ground, followed by the stepped leader, charge is brought down at a rate of 600 to 2,600 amperes (Hodges, 1954). As soon as the pilot streamer and stepped leader reach ground a conducting path between cloud and earth is established and the main stroke starts. The main stroke will transfer charge between the cloud and earth at a rate of 20,000 or sometimes 400,000 amperes. One peculiar behaviour of the main stroke is that it starts from ground and travels upwards which means that large amounts of charge are transferred from the earth's surface to the cloud. This is why it is often said that lightning travels up to the cloud rather than down. Although the main stroke only lasts for a thousandth of a second, it is visible to the naked eye and the sound or acoustic shock wave that follows is unmistakably that of a lightning bolt. The main stroke often breaks up into several subsequent strokes usually three or four per lightning flash. Lightning flashes having as many as 42 subsequent strokes have been reported. There are usually no pilot streamers or stepped leaders present between ensuing strokes in a multi-stroke flash since an ionized path has already been established after the first stroke. The stepped leader is replaced by a so-called dart leader which works its way down from the cloud in one single jump.

One of the most challenging problems in lightning research is the mystery of how lightning bolts drain charge from the thunder cloud. How does the lightning bolt connect up to the myriads of charged drops involved, and how can this be accomplished in a small fraction of a second? This is a question that has not yet been answered satisfactory. One of the best solution so far, in the author's opinion, is offered by Kasemir (1950b) who believes that the mechanism involved

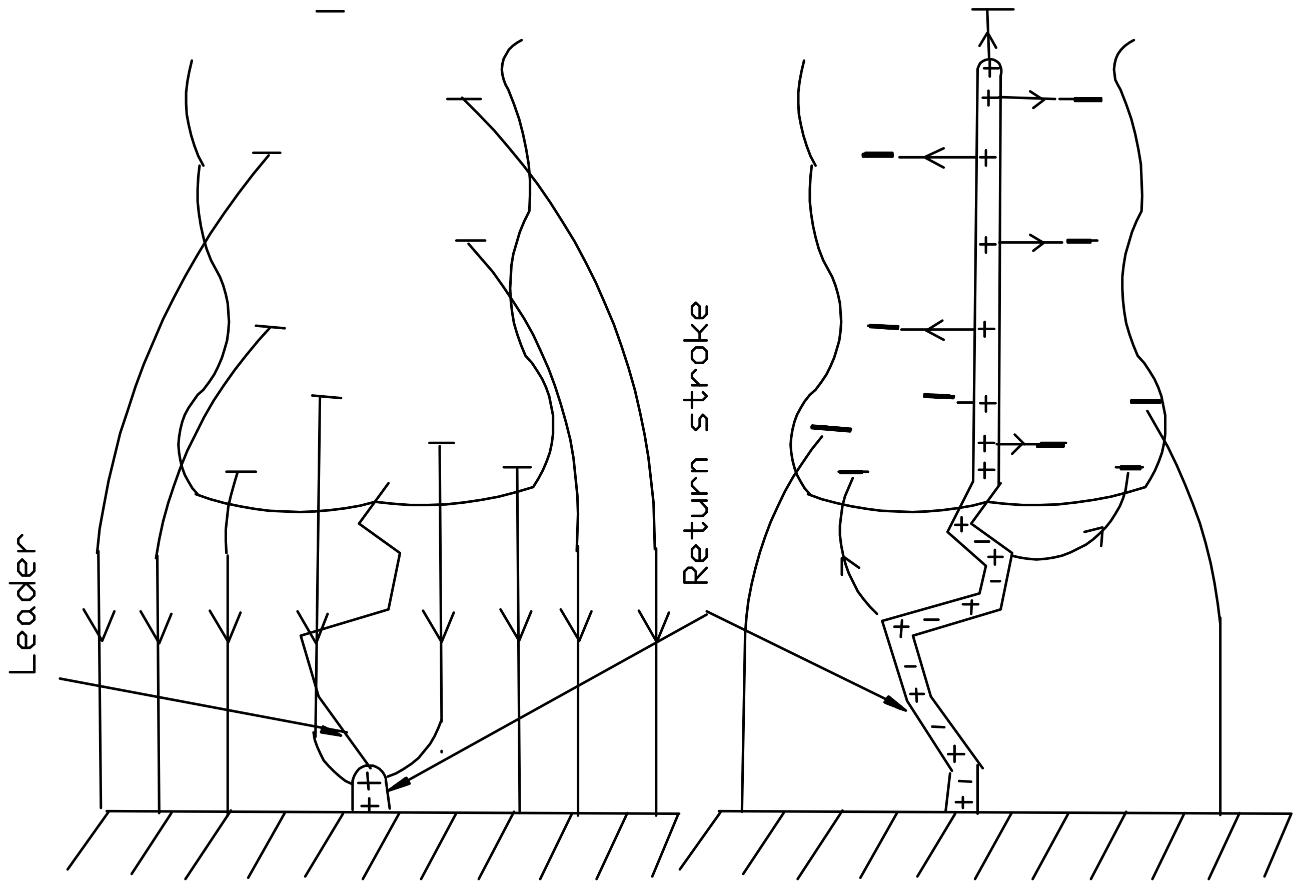

Fig. 27. Lightning discharge theory by Kasemir. (a) Start of return stroke. (b) Charge transfer by induction.

is that of induction. For example, consider a negative charge centre in the lower portion of a cloud (see Fig. 27a.) from which a leader stroke has just reached ground. Not much charge is brought down because the negative charge in the cloud is bound on small drops or precipitation particles. On the other hand the earth's surface, which is a good conductor, can easily supply positive charge up to the cloud through the ionized channel provided by the stepped leader. When the positive charge in the return stroke reaches the cloud it will penetrate the charge centre like a giant lightning rod which causes the cloud potential to drop drastically since many field lines now are much shorter (see Fig. 27b). In this way much of the electric energy is drained without contact or charge being removed from the drops in the cloud. Another way to look at Kasemir's lightning mechanism is to compare the electric potential and capacitance of the cloud before and after a lightning bolt has penetrated the cloud. A 25 coul charge centre measuring 1 km in diameter and located several kilometres above ground has a capacitance of roughly

$$C = 4\pi\varepsilon_0 R \approx 6 \times 10^{-8} \text{ Farad}, \tag{8}$$

which yields an electrical potential of

$$V = \frac{Q}{C} \approx 4 \times 10^{8} \text{ volts} \tag{9}$$

If one assumes that the charge centre is cylindrically shaped and extends $\ell = 1$ km in height then the capacity between the charge centre and the ionized channel of the lightning bolt can be estimated from

$$C = \frac{2\pi\varepsilon_0 \ell}{\ln(b/a)} \approx 9 \times 10^{-9} \text{ Farad}, \tag{10}$$

where a is the radius of the lightning channel and b the average distance of the charges in the charge centre with respect to the lightning channel. The radius of the lightning channel was taken as 1.5 m. The result is that the capacity is lowered by about 15 percent which corresponds to a charge transfer of approximately 3.5 coulombs. Since there are on average three or four main strokes per lightning flash, then the total charge transferred by a lightning flash can easily be between 10 to 15 coulombs. In fact, Kasemir's capacitor model does not only explain why the bulk of charge is moving upwards, from ground to cloud under the influence of induction, it also presents us with a $R\ C$ circuit which might explain the occurrence of multiple strokes. The time constant of the circuit (average 200 micro seconds) is the product of (9) and (10) divided by the average discharge current of 20,000 amperes. Once the capacitor is charged the lightning current will cease and the time elapsed is of course determined by the time constant. After an average length of 0.07 s (Bruce and Golde, 1942) the next stroke will follow but this time triggered by a dart leader. The ensuing stroke will form a branch which will penetrate the cloud in a different direction. More strokes might follow until the negative potential of the entire region has been drastically lowered. The induced charge transferred in this manner must slowly leak off to the individual drops by means of corona and quiet discharges that will produce numerous ion pairs inside the cloud.

In an intracloud discharge a lightning bolt starts between two charge centres where the electric field is high and where electric breakdown of air first occurs. After a small parcel of air becomes conducting from the electric break-down of the air, it will grow rapidly in length under the influence of induction. As the lightning rod type discharge grows and becomes more and more polarized, positive charge will rush towards the end facing the negative charge centre while negative charge collects at the end nearest the positive charge centre. Once the lightning bolt penetrates both charge centres, enough charge is transferred by the polarization effect to account for the observed electric field changes.

One important implication of Kasemir's discharge mechanism is that the electric breakdown of air, and formation of small ionized air parcels in the strong field region between two charge centres, can trigger lightning bolts. This means that aircraft flying in the high field region between two charge centres can become electrically polarized and trigger lightning as well. The risk of damage is therefore much greater than previously thought when it was believed that lightning would only strike aircraft in a random fashion. Pilots usually refer to two kinds of lightning strokes; the "static discharge" when lightning seems to originate from the aircraft when it is trying to rid itself of excess charge or the direct hit when lightning is believed to come from a nearby charged cloud centre. The "static discharge" is controversial in that the charge on an aircraft, as pointed out by many scientists, is by far to small (about 0.1 coul) to create a lightning bolt. Kasemir's induction mechanism, however, explains that the strongly polarized electric field on the aircraft, which causes corona discharges and electric break down of air, will supply all the charge necessary for the lightning bolt. For example, although the net charge on the aircraft is small, the amount of ionic charge produced in the surrounding air by corona is enough to feed a lightning bolt by the inductive mechanism. One cubic centimetre of completely ionized air contains as much as 5 coulomb of ionic charge.

The size of a lightning bolt or the diameter of the lightning channel is not well known. A rough idea of the channel diameter can be obtained if one uses Gauss's law to determine the maximum radius of electric break down of air due to the strong field and corona produced by the charged lightning channel. For example, an average lightning bolt which carries a current of I = 25000 amperes and propagates at a typical velocity of $v = 10^8\ \mathrm{m/s}$ will contain a charge of

$$\lambda = I / V \approx 2.5 \times 10^4\ \mathrm{coul/m}, \tag{11}$$

which by the use of Gauss's law equals a channel radius of

$$R = \lambda / (2\pi\varepsilon_0 E), \qquad (12)$$

where $E = 3 \times 10^6$ volts / meter is the breakdown field of air. It is believed that the bulk of the lightning current is confined within a small core having a cross section of about 0.15 m in diameter. The lightning channel can be pictured as narrow current core surrounded by a large ionized envelope.

4.5 PROTECTION AGAINST LIGHTNING

Modern lightning research has proved that the function of a lightning rod is not necessarily to attract lightning and lead it to ground in order to dissipate its power. Careful studies show that large amount of corona discharges occur at the point of a lightning rod before lightning strikes. The corona discharges produce numerous ions which often develop a protective dome around structures fitted with lightning rods. A large conductive dome or sphere has a smoothing effect over protruding surfaces and will lower the electric field strength in its vicinity. Experiments by Vonnegut and Moore have shown that a conducting wire supported between two mountain tops did not get struck by lightning as often as the mountain sides. In fact, the lightning seemed to avoid the wire which can be explained by the above effect that corona must produce a large diameter ion cloud around wire. This has the effect of lowering the field strength in its vicinity.

The lightning rod is an important device for protecting houses and other structures from lightning. This is accomplished in two ways. First, corona from the sharp tip of a lightning rod creates a protective ion cloud above the structure and secondly, in the event of a direct hit by lightning, the lightning rod will force the electric power to dissipate into ground and prevent damage to the building. When protecting a house or structure from lightning damage, some fundamental rules should be followed. Basically, there are two types of protection internal and external. External protection concerns the safety of the roof and sidings of a house while interior protection deals with sparks between metal object inside the house including appliances, radios and telephone lines. An effective exterior lightning protection can be described as follows:

1. Lightning rods and guard wires must be symmetrically placed over the roof to ensure uniform distribution of the discharge current.

2. Lightning rods and guard wires should be symmetrically attached to vertical conductors which distribute the discharge current to ground.

3. A good ground connection, far away from under-ground cables and pipes, must be established in order to let the energy dissipate into the earth's surface as effectively as possible.

4. No point on a roof should be further than 10 m (30 feet) away from a lightning rod or guard wire.

5. All large metal objects on the roof should be electrically connected to the system.

6. Any large protruding non-conducting structures or objects on the roof should be fitted with an individual lightning rod.

7. A building should have at least two vertical conductors to ground.

8. Sharp bends or curves in the conductors should be avoided since they might cause unnecessary induction and build-up of sparks.

9. Large metal objects on the outside walls such as balconies and fire escapes must be connected to the system.

The recommended cross sectional area of guard wires and vertical conductors should be at least 2.5 mm^2 (0.04 in^2)and twice that area for the buried wires that serve as ground connections. Fig. 28 shows several different ways of protecting houses and similar structures. Fig. 29 demonstrates a simple lightning protection for sail boats. Thousands of people around the world are killed by lightning every year. Most fatalities occur in open fields and usually when lightning strikes within a range of 50 to 100 metres of a victim. The danger is that when lightning strikes ground a tremendous amount of current radiates out in all directions from the point of impact. Since the current travels on the surface, which offers a certain electric resistance, a voltage drop will develop which can easily reach 1,000 volts per metre 100 metres from the point of impact. A person walking might bridge a lethal voltage in one step or could easily be thrown off his feet by muscular contractions from the electric shock. It has often been said

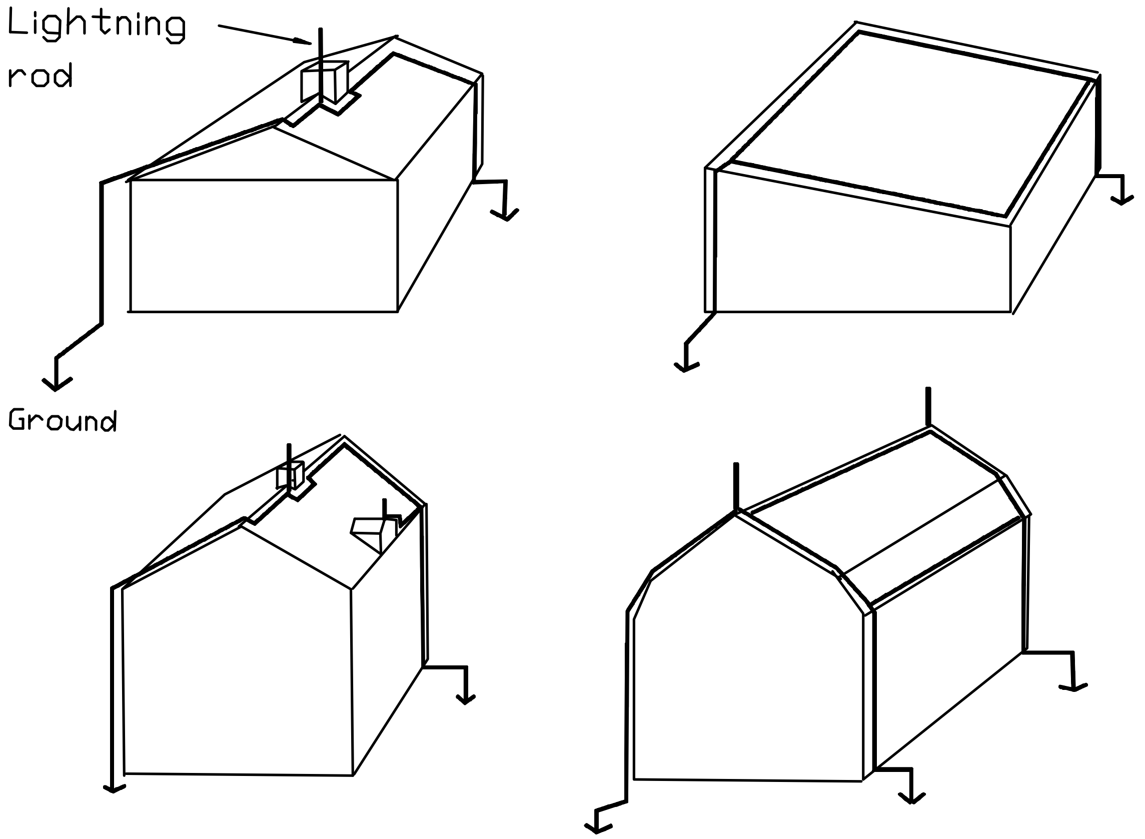

Fig. 28 Lightning protection for houses.

that it is safer to run than to walk across a field during an overhead lightning storm. This might not be far from the truth since only one foot would be in contact with ground in case lightning strikes. Lightning often strikes trees, consequently one should never take shelter under trees, near power lines, *etc*.

4.6 THE ELECTRIC CHARGING OF CLOUDS

Numerous observations and measurements have shown that a thundercloud theory must satisfy certain conditions:

1. It must explain a positive charge in the upper region of the cloud and a negative charge in its lower portion and during the

later stage in the cloud's life cycle it must justify the appearance of a small pocket of a positive charge near its base.

2. The theory must clarify why it takes approximately 20 min. to generate enough charge for the first lightning flash and only a few second for the ensuing flashes.

3. The process must be capable of separating a charge of at least 1,000 coulomb per thunder cloud during an average life time of 30 minutes. A typical diagram of a thunder cloud is shown in Fig. 30.

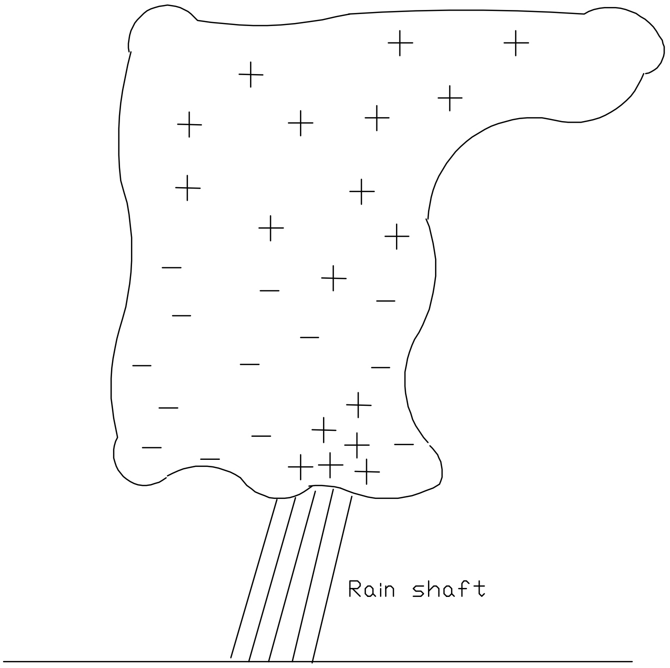

Fig. 30 Typical charge distribution in a thundercloud.

Many theories have been developed ever since Franklin's and D'Alibard's discoveries over 200 years ago. A theory must resort to some kind of energy source and most thundercloud theories seem to fall within two such categories, namely that of gravitational energy and energy provided by convection. Gravitational mechanisms rely on the gravitational potential energy available as precipitation particles fall from the upper part of a cloud to its lower region. Convection mechanisms make use of energy supplied by the intense updraft winds in thunder clouds.

Most theories such as the Wilson mechanism, influence charging, icing and ice splintering mechanisms all fall under the gravitational process. Charge is produced on precipitation particles by one of the above processes in which negative charge is preferentially attached to larger and heavier drops which fall down and separate from the smaller drops causing a large build up of the electric field within the cloud. One serious problem with gravitational mechanisms is that according to the data presented by Israel (see sec. 4.2 and 4.3) an average thunderstorm cell which contains 8×10^8 kg of water must produce 1.7×10^{13} joules of electric energy, which is not possible. Simple calculations show that the gravitational energy available in a cell which contains 8×10^8 kg of water has a potential gravitational energy of $0.6\,mgh / 2 = 1.2 \times 10^{13}$ joules (g is the gravitational acceleration, h the average vertical separation of roughly 5 km between the charge centres and m *is* the total water content). This means that there is not enough gravitational energy available to account for the electric energy present in the cell. If the above reasoning holds true then all charging mechanisms which rely on gravitational potential energy can be ruled out. However, more careful evaluation of existing data and more measurements are needed before such a decision can be made.

Convection mechanisms on the other hand can easily provide the energy and charge needed through the continuous ventilation of near stationary drops. There are essentially only two theories developed so far which are based on convection, the theory by Grenet (1947) and the electrochemical mechanism (Wåhlin 1973). Grenet and later Vonnegut (1955) suggested that natural positive space charge is brought in from below the cloud and carried to the top by convective updraft currents. The positive charge at the top of the cloud will attract negative ions from the outside air volume which are captured by down draft currents and thus assumed to be brought to the bottom of the cloud. As the process continues, the increased electric field will produce more positive ions under the cloud by corona point discharges at the earth's surface which in turn are carried through to the top by updrafts. One objection (Chalmers, 1957) is that it is difficult to understand how the updraft and downdraft currents can distinguish between negative and positive ions in a way that only negative ions can be transported by down drafts and positive ions by updrafts.

In the electrochemical charging mechanism convection currents simply bring natural ions of both signs in from outside and ventilate them through the drop population of the cloud. However, negative ions which are extremely reactive attach themselves to drop surfaces at the bottom of the cloud while the inert positive ions sieve through and are carried by the updrafts to the upper regions. The electrochemical charging mechanism, which is described in Chapter 3, is very effective and despite criticism by Vonnegut, Moore, Griffith and Willet (see section 2.7.3) is the only process which can easily be modelled in the laboratory. The diagram in Fig. 31 shows such a model constructed from two clumps of steel wool. The two sections of steel wool, one representing the bottom and the other the top of a thunder cloud, are electrically insulated from each other. A fan blows air through the cloud model to simulate the updraft winds inside a thunder cloud. A radioactive alpha particle source (Po 210, 500 micro Cu) near the fan feeds positive and negative ions at equal number into the cloud model. Negative ions are immediately captured by the electrochemical process in the bottom section while the inert positive ions pass through and reach the upper steel wool section where they stop together with the air flow. In a model the size of a large football over one hundred volts of charge separation is readily achieved. A small neon light, connected across the cloud model, demonstrates the lightning discharge in a realistic manner. The polonium 210 is readily available from several mail order suppliers and does not require a license.

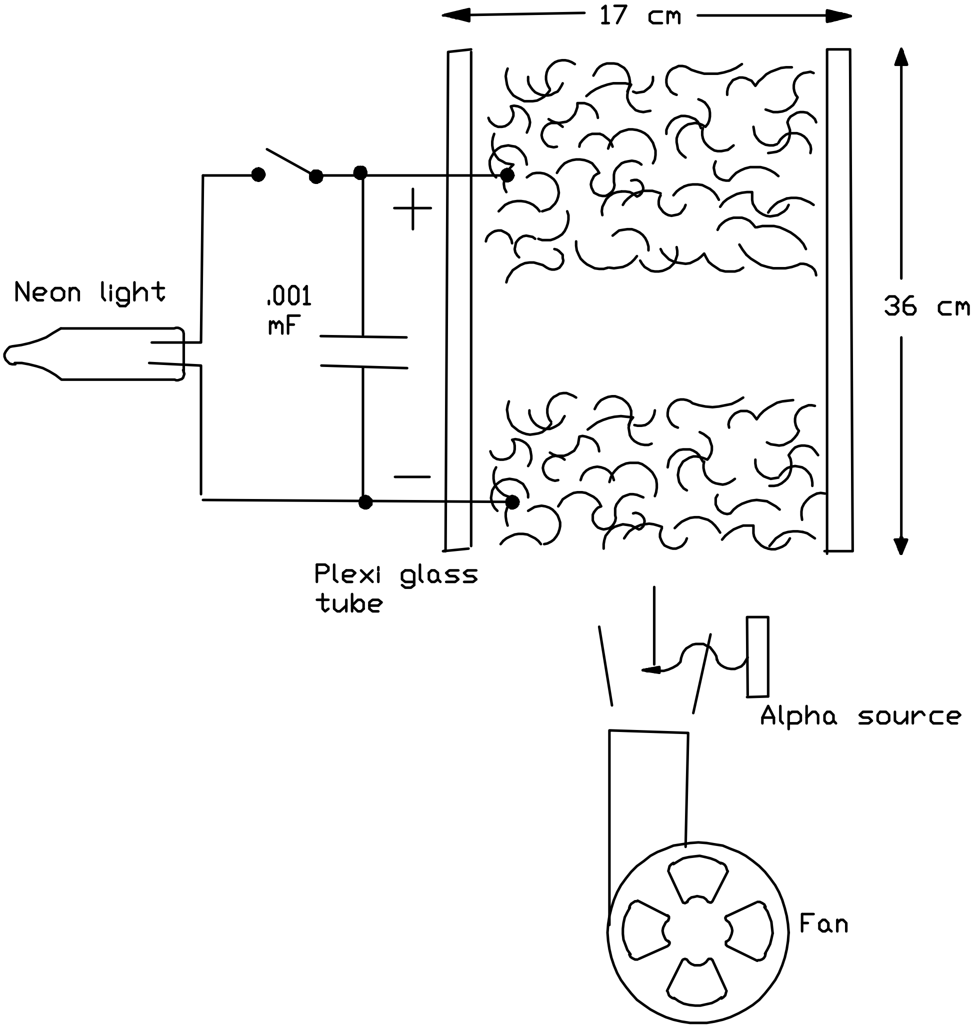

Fig. 31 Laboratory model of thundercloud.

The electrochemical charge separation in clouds has been theoretically scrutinized by Pathak, Rai and Varshneya (1980) who determined that enough charge can be separated from atmospheric ions within 10 minutes to trigger the first lightning discharge. Once lightning has occurred numerous ion pairs are created by the discharge itself which will increase the charge rate drastically to allow for ensuing lightning discharges to occur within seconds of each other. In the dissipating stage when down drafts begin to appear in an organized way, the charging process can reverse and form a small positive charge centre near bottom of the cloud. This explains the small pocket of positive charge near the cloud base which is often observed by investigators (see Fig. 30).

4.7.1 BALL LIGHTNING

Ball lightning is a controversial subject and such a rare phenomenon that many investigators in the field still doubt its existence. Many sightings have been reported dating back hundreds of years, but no convincing photographs or scientific records have ever been produced. Nevertheless, ball lightning has intrigued a great number of reputable scientists and has resulted in many exotic theories. Certain fundamental characteristics of ball lightning has been agreed on which can be described as follows: The geometrical shape of ball lightning is that of spheroid with a diameter of 10 - 20 cm although diameters as small as 2 cm and as large as 150 cm have been reported. The colour of ball lightning varies from white, bluish-white, greenish-white, red or orange-red. The light or glow seems to be steady throughout its duration which might be a few seconds to several minutes. Ball lightning might decay slowly and faint out or disappear in a sudden explosion often causing severe damage. Ball lightning has been reported to pass through window panes and walls, a phenomenon which is difficult to conceive. In most cases it moves silently above ground or along fence wires and power lines. Occasionally it is accompanied by small sparks and corona discharges which indicate the presence of electrostatic charges. Ball lightning appears only during severe thunderstorms that produce intense lightning discharges. It is believed that ball lightning might originate from the ionized lightning channel of super bolts.

Small electric plasma balls have often been observed in submarines when battery banks have been accidentally shorted out. The high short-circuit currents cause intense arcs to appear across contacts of reverse current relays which are fitted with magnetic blow-out coils. Occasionally a fire ball is blown out which will float off into the engine room and remain visible for a short time while decaying by the normal electron-ion recombination process.

As previously mentioned, there are many theories proposed in order to explain ball lightning (Barry, 1980). One such theory is the ring current plasmoid model which is derived from observations and experiments performed with submarine batteries (see Silberg, 1965). The ring current model does not mention what mechanism creates a ball lightning but deals more with the decay time of the plasma itself. Other more exotic theories are the standing wave model which is based on microwave resonance and the crystal model which treats the problem from a quantum mechanical point of view.

4.7.2 THE QUANTUM MODEL

The quantum model is interesting in that it tries to explain how a completely ionized plasma is maintained at very low temperatures, less than 340 C. Neugebauer (1937) used quantum mechanical arguments, derived from well-known free-electron gas models, to show that once a plasma ball has been created it will require very little energy too sustain itself. For example, from the black body radiation of such a plasma it can be determined that a completely ionized ball of 10 cm in diameter would require less than 24 watts and a 20 cm ball about 90 watts to remain completely ionized. The quantum model does not explain where the power comes from that generates the heat or how the plasma was created in the first place.

4.7.3 THE STANDING WAVE MODEL

Cerrillo (1943) and Kapista (1955) advanced a model of ball lightning in which the ionized plasma is produced and maintained by radio frequency oscillations. It is believed that a standing wave is created inside a plasma where the size of the plasma is equal to one quarter wavelength of its cavity frequency. If the radio frequency is suddenly cut off, the ball will produce a weak shock wave when collapsing. If the

RF energy is gradually diminishing then the ball will slowly faint away without any drastic after effects. How to explain the mechanism that is responsible for producing such a high intensity RF field remains a problem.

4.7.4 THE RING CURRENT MODEL

Fire balls formed in engine rooms of submarines have led to the speculation that ring currents might be responsible for the production of plasmoids with reasonable long life times. The long life time is based on the idea that a plasmoid must have a very low ohmic resistance R and a certain amount of induction L, due to the magnetic field of the ring current. The time constant $t = L/R$ is therefore a measure of the plasmoids life time. Fig. 32 shows a diagram of the plasmoid itself. Also, it is not clear how such a ring current might be produced and how it can obtain a spherical shape.

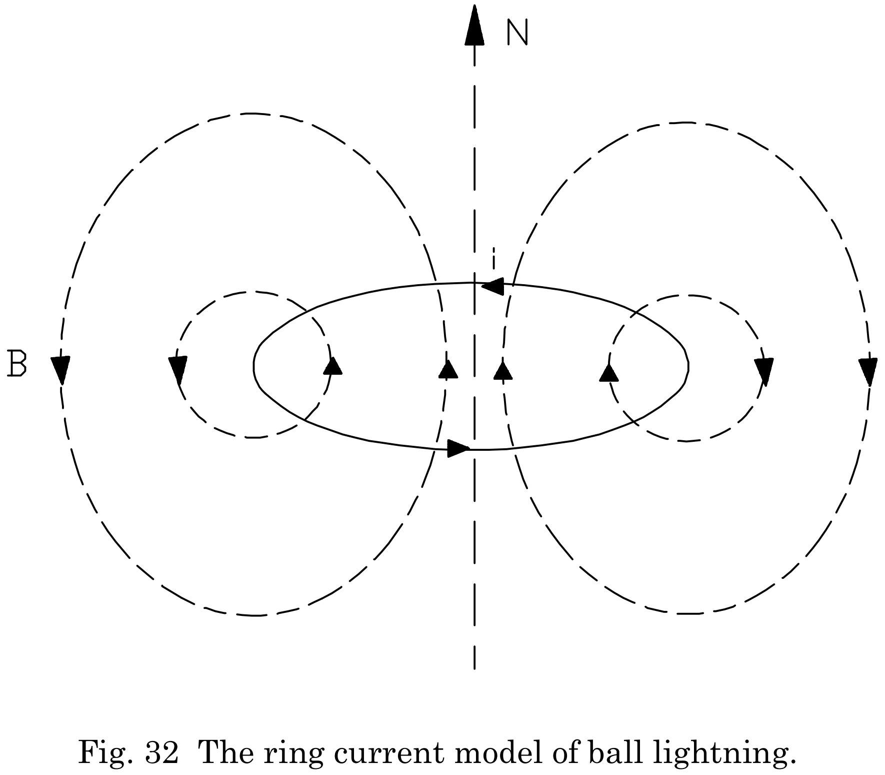

Fig. 32 The ring current model of ball lightning.

4.7.5 THE PINCH EFFECT

The pinch effect is a well known phenomenon. It explains how lightning bolts sometimes break up into small balls called bead lightning or pearl lightning, an event which has been observed by the author in both Africa and Sweden. The strong magnetic field produced by the lightning bolt current can force the flow of charge to bend inward towards the centre of the lightning channel to such an extent that it will choke and pinch itself off. The pinch effect can be better understood if one examines Ampere's law, see Fig. 33, which states that the attractive force between two parallel conductors, which carry currents i' and i" respectively, is equal to

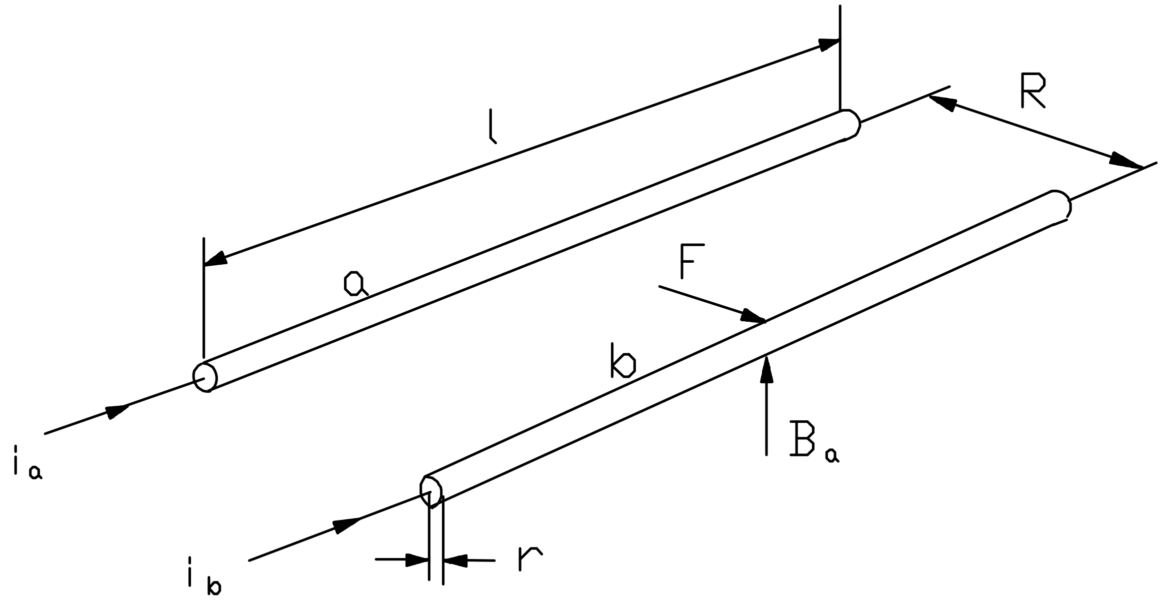

Fig. 33 Two parallel wires which carry currents in the same direction attract each other.

$$F = \frac{\ell i' i'' \mu_0}{2\pi R} = \ell i' B, \tag{13}$$

where ℓ is the length of the current elements which are separated by a distance R. The magnetic field generated by one current at the site of the other is B and μ_0 is the permeability constant.

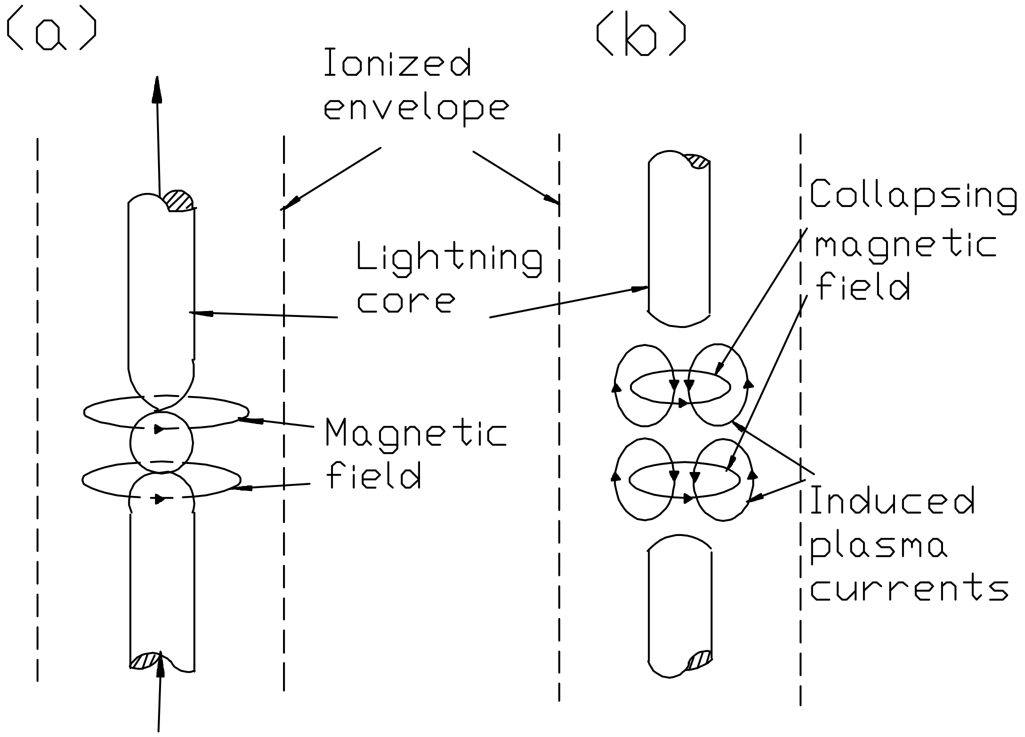

Fig. 34 The pinch effect causes the lightning core to break up into small segments (bead or pearl lightning). permeability constant.

In a lightning channel, where numerous charges or current elements move in the same direction, a mutual attractive force is developed which will cause the lightning channel to contract, see Fig. 34 a. The force of contraction can reach a magnitude where the lightning channel gets pinched off and becomes separated into small spherical sections (beads or pearls) see Fig 34 b. Once the flow of charge is pinched off, the electric current will cease which causes the magnetic field to collapse. The collapse of the magnetic field, on the other hand, will induce eddy currents in the ionized plasma, isolated by the electromagnetic pinch effect, which will maintain the electric discharge and prevent the magnetic field from rapid decay. The plasma ball formed can be pictured as a magnetic ring field trapped inside a toroid electric plasma current, see Fig. 35. One of the conditions required is that the plasma must be completely ionized and super-conducting in order to offer minimal resistance or ohmic loss. Any presence of neutral particles will cause recombination and rapid decay. A collision with a conductive object such as an iron stove, for example, could drastically neutralize the plasma ball in an explosive manner. The theoretical model described implies that that a ball 10 cm in diameter, completely ionized, would contain an ionization energy o 7 kilo joules and eight times that amount for a 20 cm diameter plasma ball. The field of induction set up by the plasma current is

$$B = \mu_0 I, \tag{14}$$

where I is equal to the lightning current at the moment of pinch-off. The energy density of the trapped magnetic field is

$$U_B = \tfrac{1}{2}\frac{B^2}{\mu_0}. \tag{15}$$

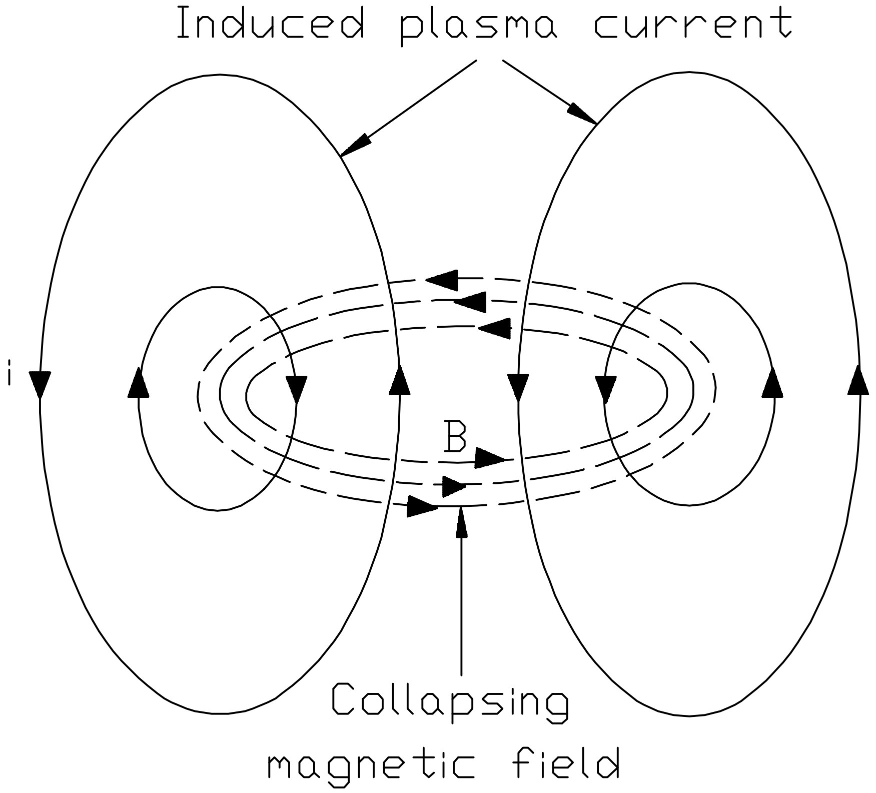

Fig. 35 Magnetic ring field model of ball lightning.

The energy of the magnetic field in a 20 cm diameter ball, produced by a super bolt delivering 400 kA peak current, is equal to about 400 joules. Using Neugebauer's argument that 20 watts is sufficient to maintain a 20 cm plasma ball (see 4.7.2) means that 400 joules will make the plasma ball last for about 20 seconds.

CHAPTER 5

FAIRWEATHER PHENOMENA

5.1 EXPERIMENTS AND OBSERVATIONS

After Lemonnier and Beccaria discovered the fairweather electric field by probing the atmosphere with poles and stretched wires, the first considerable advance was made by de Saussure (1779) who introduced several new methods of measurements. De Saussure constructed an electrometer consisting of two elder pith balls suspended from silver wires inside a glass jar with metallic shielding. When the balls were charged to the same polarity they repelled one another and the amount of deflection was a measure of the electric intensity from a source brought in contact with the silver wires. By raising and lowering an antenna which was connected to the electrometer, de Saussure could show that the electric potential in the atmosphere increased with altitude. Another clever experiment by de Saussure was to throw a lead ball, which was connected to the electrometer by a thin wire, straight up in the air braking the wire and electric connection. The ball, after reaching a certain potential, would take its charge with it and leave an opposite charge behind on the electrometer. De Saussure realized that the electrostatic charge induced on his antennas was caused by a positive static charge in the atmosphere above. He is also believed to have been the first to discover the systematic annual change in the fair weather field, see section 1.5.

One interesting experiment involving the use of kites was performed by Mahlon Loomis, a Washington D.C. dentist, during the period 1862 - 1873. Loomis used two kites at the end of stranded bronze wires about 600 feet in length. The wires were both grounded through sensitive galvanometers but the ground connections could be broken by means of telegraph keys. Loomis was able to transmit morse code messages from one antenna to the other over a distance of up to 16 miles without the use of any external electric source. In the early 1870's Loomis was supposed to have achieved voice communication using a Berliner's microphone. He applied for government funds for a classified military project, but since the Civil War was over, Congress would not appropriate the money. What is important is that Loomis must have been first to achieve wireless communication but obviously not by radio but by disturbing the electric fairweather field. A member of the family, Thomas Appleby, has published a book on Loomis' experiments and copies of patents issued (Appleby 1967).

In the beginning of this century it was discovered that ions cause the atmosphere to be conductive and new theories were needed to explain how charges on the earth-atmosphere system are maintained. It has been suggested that the earth's rotation in its own magnetic field could produce a magneto effect which would drive the electric fairweather circuit, or that evaporation of water from the earth's surface might charge the earth negatively and the water vapour positively by some unknown process. In fact, Volta (1800), advanced an electrification theory based on vapourization and condensation of water in order to explain charge production in thunderclouds. Today, although the question still remains open, there are primarily two theories dealing with the problem of the origin of the electric fairweather field. One is the closed circuit hypothesis which asserts that all thunderstorms around the world recharge the earth-ionosphere system. The other theory is the electrochemical process which is an electrostatic mechanism based on the preferential capture of negative ions by the earth's surface. The amount of charge produced by all thunderstorms around the earth at any given time is certainly adequate for replenishing the fairweather charge and the variations of the fairweather field as a function of GMT seems, to a certain extent to follow the variation in the world-wide convection pattern as shown in Fig. 15. The electrochemical charging mechanism, on the other hand, suggests that if a sphere the size of our earth is ventilated by ionized air then, by extending the curve in Figure 23, it will charge to approximately one million coulombs, a value that conforms with the measured charge on earth. The curve, of course, shows the charge on water surfaces, but it should be remembered that two-thirds of the earth is covered by water. Also, the earth's surface is constantly being ventilated by winds carrying natural ions which are supplied at a steady rate by cosmic and radioactive decay. The excess positive ions left behind near the earth's surface are carried aloft by convection and by eddy diffusion, thereby mixing through the atmosphere to heights of several kilometres. Lifting the positive ions from near ground to higher altitudes stretches the electric field lines and increases the potential. This is analogous to the contact potential experiments performed by Lord Kelvin (see section 3.2) in which the potential is increased by separating the two metal plates in his condenser apparatus. The electrochemical charging mechanism is strongly dependent on convection and is also expected to follow the world-wide convection pattern as shown in Fig. 15.

About 90% of the electric fairweather field is confined to altitudes of less than two kilometres, or that part of the atmosphere referred to by meteorologists as "the mixing region". Integrating electric field strengths up to a variety of heights will give the values of electric potentials at varying altitudes. At an altitude of two kilometres, for example, this potential is normally about +200 kilovolts with respect to earth. At the University of West Virginia a team of physicists have managed to build an electric motor driven by the electric fairweather field utilizing an antenna extended high into the atmosphere (Jefimenco, 1971).

Since the electric fairweather field is enhanced by convection and mixing in the fine weather atmosphere, measurements of electric field strength at varying altitudes and at diverse locations may give important information about the atmospheric mixing processes in terms of local weather forecasting. Large scale forecasts might also be possible because the electric fairweather field exhibits a slight variation every twenty-four hours that is synchronous for all parts of the world. The diurnal fluctuation is linked to the fact that continental land masses of various sizes are exposed by the daily rotation of the earth to the heat of the sun and this results in convection and enhancement of the electric field (see Fig. 15).

Many other phenomena in the atmosphere can be explained by the electrochemical effect. For example, airplanes in flight, are subject to ventilation by atmospheric ions and thus charge accordingly. A Boeing 747 should reach a potential of over -100 kV by rough estimation based on Equation (7). A large body such as a zeppelin could reach a potential of several hundred thousand volts in the naturally ionized atmosphere, making a voyage in a hydrogen airship a highly dangerous venture, as proved by the mysterious disintegration of the Hindenburg in 1937.

Charging also occurs inside combustion chambers of engines where ions are formed at high temperatures. By means of the electrochemical process, ions of one sign (normally negative) are preferentially captured by engine walls, permitting those of opposite charge to escape in the exhaust stream. Exhaust charging is a common phenomenon in our modern world. Not only do aircraft charge by this process but motor vehicles on rubber tyres become electrostatically charged even at stand still while idling. Exhaust gas from engines and smoke stacks produce excessive positive space charge over heavily populated areas. Aircraft flying through such areas during landing approaches become positively charged in contrast to what is normally experienced during regular fairweather flights. The explanation is that if an aluminium fuselage is subject to ventilation of an abnormally high positive to negative ion ratio, where $N^{+} / N^{-} = 1.3$ or more then, according to Fig. 11, the aircraft must charge positively.

Exhaust charging also plays an important role in geophysical phenomena such as volcanic eruptions which often produce lightning and during earthquakes where a glow or earthquake light is emitted along fissures and cracks.

It is difficult to say whether atmospheric electricity has any practical applications at the present time. The structure of the fairweather field and how it is linked to convection and turbulence in the atmosphere might be of meteorological interest. The fairweather field as an energy source is too feeble for practical purposes and will only yield about 1μwatt per m^2 at the earth's surface, or approximately one billion times less than solar power.

Also worthy of consideration is the fact that for the past 50 years scientists have been looking for physiological effects caused by ions and electric fields in the earth's atmosphere. Many experiments have already been performed that seem to show such a relationship. However, one still lacks concrete physical evidence and much more work is needed before one can determine the significance of atmospheric electricity with respect to one's state of health. There is also a growing interest in planetary atmospheric electricity as a consequence of data sent back from space probes.

5.2.1 EXHAUST CHARGING

Lord Kelvin was aware of the "wonderful agency in flames and fumes" causing deviations in his electrometer readings when passing through his condenser plates. Earlier (c. 1800) Volta discovered that static charges on conductors changed rapidly when exposed to candle flames or lit fuses. Modern science explains that ions produced from combustion increase the conductivity of the surrounding air causing potential gradients to change more rapidly. An increase in ion population also enhances the electrochemical charging effect. In combustion chambers of engines, where numerous ions are formed, the electrochemical charging effect often becomes a nuisance and in some cases a hazard. For example, fuel might ignite while attempting to refuel a charged vehicle or aircraft. During combustion negative ions are usually captured by the engine walls while the positive ions are carried away by the exhaust stream. The result is an accumulation of negative charge on the vehicle. Fig. 36 shows an experiment performed by the author with a diesel car blocked up on insulators. A charging current of 2 micro amperes was registered at fast idle of the 2.25 litre engine. Similar experiments were carried out on small aircraft and negative charging currents of up to 10 micro

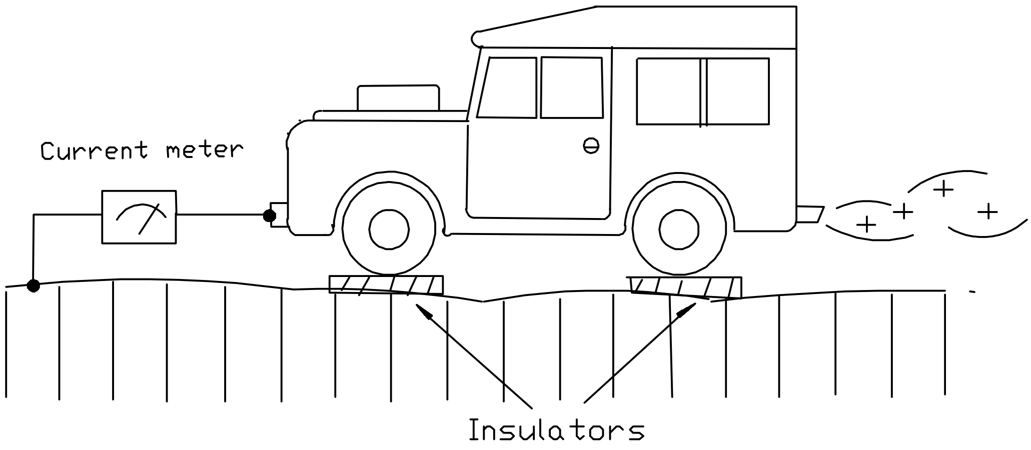

Fig. 36 Exhaust charging of a motor car.

amperes were measured. Exhaust charging can easily produce static potentials of several thousand volts. Severe electric shocks can be obtained from large aircraft not fitted with static eliminators or by touching metal hooks lowered from hovering helicopters.

5.2.2 VOLCANIC ERUPTIONS

Volcanic plumes charge to high potentials and, just like thunderstorms are accompanied by a display of lightning discharges. Not much is known about the charging mechanism involved and very few measurements are available that can shed light on the electric structure of such plumes. Space charge measurements at ground level near volcanic eruptions reveal negative charge on precipitating ash particles which, according to the mirror-image effect (sec. 2.5), means that there is positive charge on the plume above. Opposite signs have been reported and the conclusion is that ash particles from different

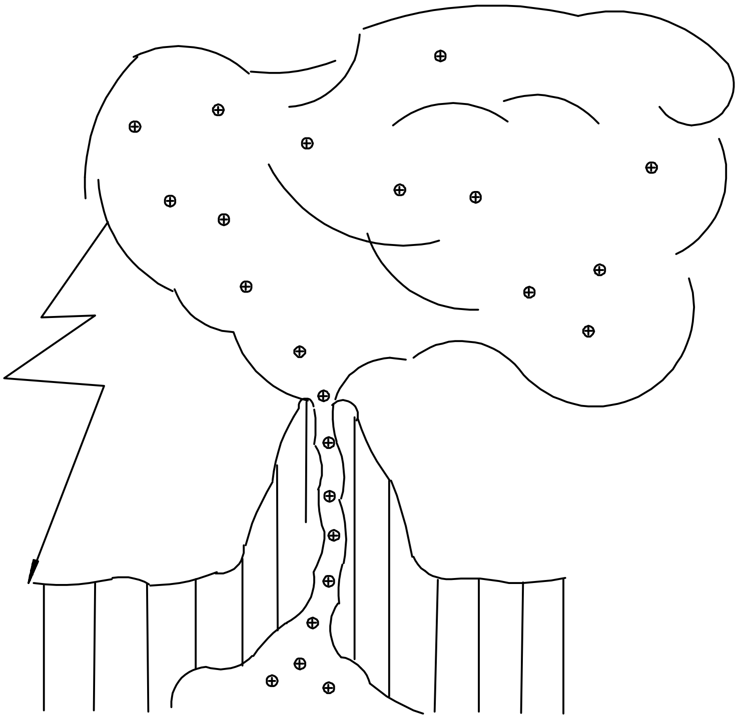

Fig. 37 Electrostatic charging of volcanic plume.

volcanoes charge differently. It is difficult if not, impossible to determine the dominating sign of charge in plumes from ground measurements because sign reversals, due to lightning discharges and mirror-image effects, are always present.

It has been suggested that volcanic plumes charge by frictional effects between small and large ash particles and that separation of charge is enhanced when larger particles fall out of the plume. Other charging effects to be considered are convection mechanisms and exhaust charging. Convection and condensation of water vapour as in regular thunderstorms can also explain the build-up of charge in the plume. Exhaust charging might play a dominating role since numerous ions must be present in the hot interior of the volcano. Negative ions can be expected to be adsorbed to the inside walls before reaching the earth's surface while the more inert positive ions are carried up with the plume, see Fig. 37.

Electric measurements during volcanic eruptions are obviously very difficult to perform if not dangerous. Also, volcanic eruptions are not as common as ordinary thunderstorms and data is, therefore, very sparse.

5.2.3 EARTHQUAKE LIGHT

Earthquake light is a rare phenomenon and its existence is still being questioned by some scientists. It was not before 1965, during the Matsushiro earthquakes in Japan, that actual photos were obtained of earthquake light (Yasui, 1968 and 1971). Earthquake light has been observed as a faint red and white glow for hundreds of miles around just before the earth begins to shake and crack along a fault zone. There has been much speculation on what might cause earthquake light. One fact is certain, that the light must come from atoms that have been ionized or excited by some mechanism triggered by the earthquake. The light is emitted when a detached or excited electron falls back again into its stable orbit around the atomic nucleus. Ionizing collisions in air, between atoms and particles or between atoms and photons, by far outnumber exciting collisions. Ionization of air molecules, to the extent where the sky will glow for miles around, could be caused by corona discharges near the earth's surface or by ionized exhaust gas escaping from the hot interior below the earth's crust. It has been suggested that frictional heating of a shear zone will occur during an earthquake and that the frictional heat will lead to vaporization of water in and near the shear zone (Lockner *et al*, 1979). The result would be a drastic increase in the electric resistivity of the rock throughout the shear zone coupled with some sort of charge separation due to the evaporation of water. After enough charge has been collected in the shear zone, corona discharges along its top edge would stream into the atmosphere like St. Elmo's fire. One problem, however, is that corona discharges draw a great deal of current ($100\mu A$ per cm^2) and it is difficult to understand how such a current can be supplied over a highly insulating rock surface. Also, corona is quite a noisy phenomenon unlike silent earthquake light.

Other theories take into account the piezoelectric effect in which strong electric fields are presumed to form in quartz rich crustal rocks subject to high mechanical pressures (Mitzutani et al 1976). Again high electric fields along the fault zone would create corona and St. Elmo's fire. One interesting idea is that the sparks and crackle from piezoelectric discharges in the interior would create electromagnetic radiation, similar to that of old spark transmitters used before the invention of vacuum tubes and transistors, to the extent that the air above the earth's surface would ionize and glow. The power of the electromagnetic radiation must be high enough to ionize air and make it glow. One would expect that such a powerful electromagnetic radiation, that will cause electric breakdown of air, would cook everything else in sight and heat the earth’s surface to extreme temperatures.

Perhaps the explanation of earthquake light has nothing to do with electrostatic charging but simply the escape of gases such as the radioactive element radon. According to the Handbook of Chemistry and Physics there is about 1 gramme of Radium per square mile of soil to a depth of 6 inches which releases radon into the air. During an earthquake, radon is released from considerable depths and brought to the earth's surface in large amounts. Each radon atom is capable of producing one million ion pairs. The handbook states that when radon is frozen below its melting point it will exhibit a brilliant phosphorescence which becomes yellow as the temperature is lowered and orange-red at the temperature of liquid air. The light is from ionizing collisions between alpha particles and atoms. It can be expected that when large quantities of radon escape it might be accompanied by other foreign gases trapped far beneath the earth's surface. The gases, unnoticed by humans, could easily be detected by animals and the unfamiliar scent might have a disturbing effect on their behaviour. It is believed that the Chinese are able to predict earthquakes and it is well known that they are monitoring animal behaviour for this purpose.

5.3 BIOLOGICAL EFFECTS

The exposure of human and animals to ions and strong electric fields has only very recently become an important issue in many countries. The Soviet Union, for example, has very rigorous rules and regulations concerning the exposure of workers to electric fields in power stations. In Sweden studies have been carried out on the effects of ions and strong electric fields on humans under different working environment (Lövstrand et al 1978 and Backman, 1979). Many other countries are and have been involved in similar research. The exposure to electric fields is in itself not considered important, but the production and movement of ions in electric fields are of chief concern. Ions carry charge to the body; they are also inhaled and trapped in the respiratory system. The question is; do ions effect our physiological or psychological well being? So far, numerous tests have been performed in different environments where ion concentrations and electric fields have been changed under controlled conditions. ECG and EEG recordings, blood and urine tests as well as blood pressure and neurasticthenics (headache, nausea, insomnia, tiredness) have been monitored by many investigators but no conclusive results have ever been reported. There are many who believe that negative ions affect them in a pleasant way and that an excess of positive ions have an adverse effect. The author knows of physicists who installed negative ion generators in their cars and which are turned on during long trips in the event their wives and children become rowdy. One atmospheric electrician confided that occasionally he turns on a positive ion generator, which puts his wife to sleep, so that he can watch a TV programme of his own choice! It has been established that ion currents produced on the human body as a consequence of the electrostatic fields, are too insignificant to

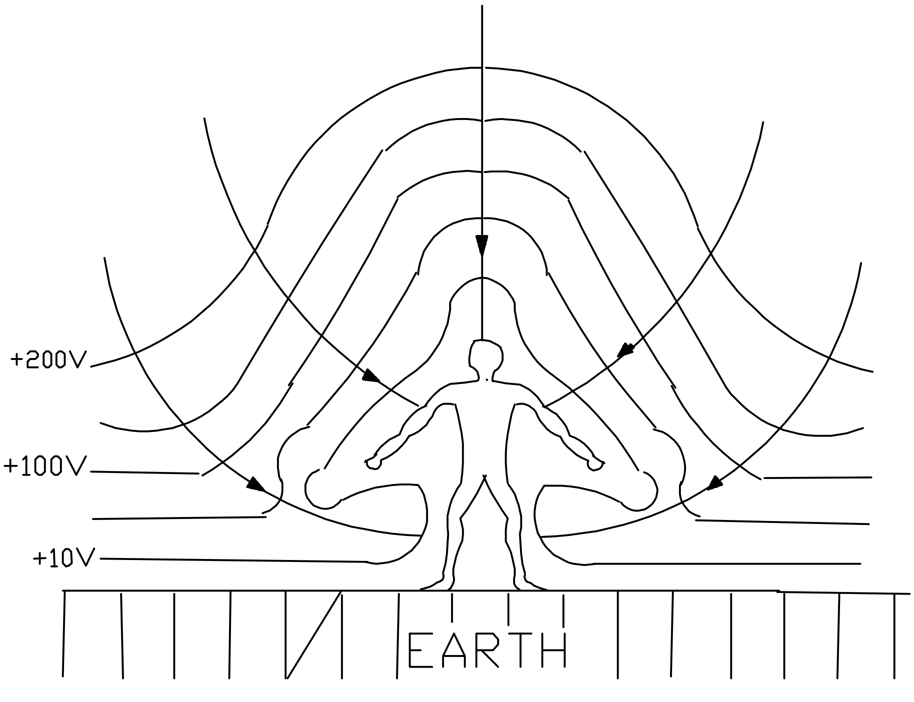

Fig. 38 A person exposed to the electric fairweather field.

cause any noticeable effects (Backman, 1979). A person exposed to the normal fairweather field, see Fig. 38, will perhaps collect a positive ion current of 10^{-13} ampere on his head. Internal brain currents are millions of times larger and it is hard to believe that the external ion current will have any effect on the function of the brain. The effect of inhaled positive and negative ions on the respiratory system is unknown. It is possible that negative ions might have a stimulating effect on the cilia in the alveoli. The amount of ions inhaled and the sign, whether negative or positive, is strongly dependent on the electrostatic charge carried by the person in question. For example, a person walking across a carpet in an office might charge negatively to several hundred volts. The strong electric field will repel negative ions and allow only positive ions to enter the respiratory system. In fact Bach (1963) has demonstrated this effect using an insulated mannequin head biased at different electric

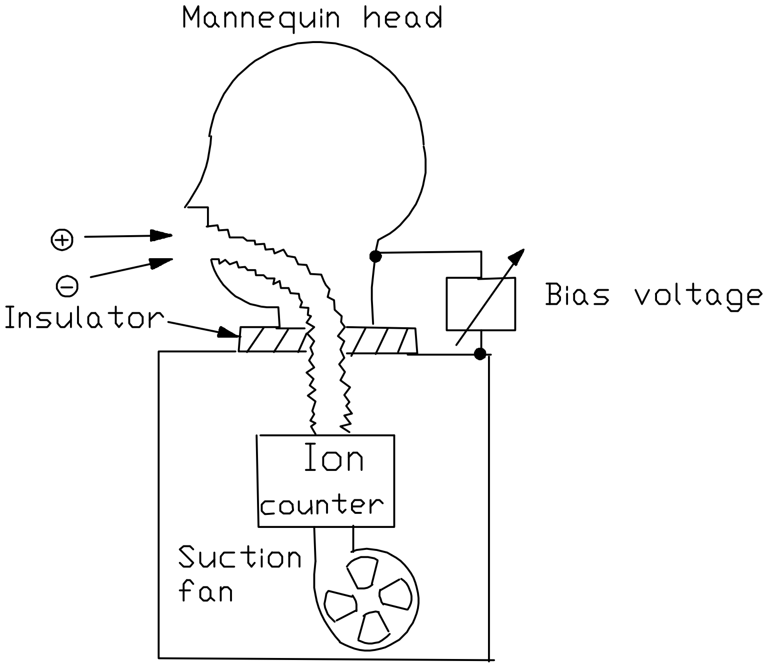

Fig. 39 Apparatus intake through the respiratory system.

potentials, see Fig. 39. The result is shown in Fig. 40 where N' represents the increase in either positive or negative ions as compared to the normal ion ratio at zero bias.

The belief that ions might have a bioelectric effect on humans and animals probably started in the Alps of Europe. It has always been noticed that during the föhn when dry winds sweep down the mountainside some people become depressed or develop head-aches and that dogs and chicken tend to hide away. It has also been observed that the positive space charge or positive ion concentration in the atmosphere during the föhn is very high which is probably one reason why positive ions are blamed for causing discomfort amongst mountain villager. Another observation is that warm mountain winds, like the föhn, are very dry which can cause considerable discomfort as explained by Tromp (1969).

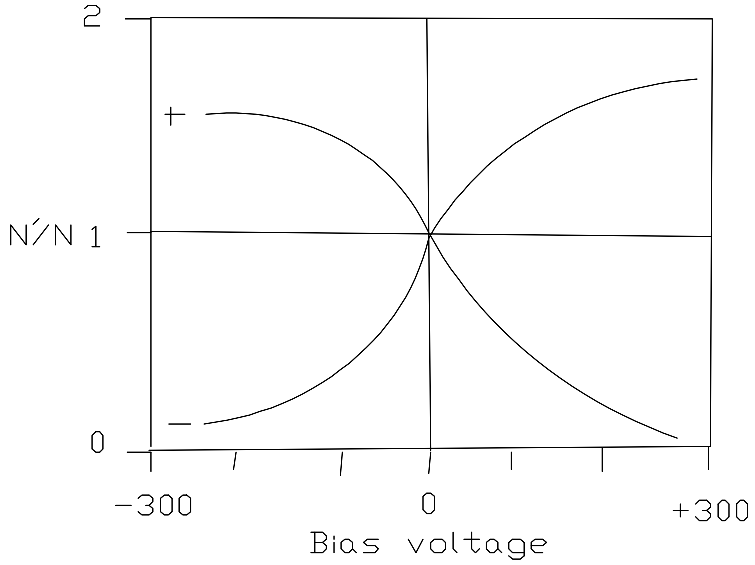

Fig. 40 Ratio of charged ions inhaled at different bias voltages.

Warm mountain winds occur when cold air masses pass over mountain ranges, and when the cold heavy air reaches the other side it falls down, compresses, and heats up again. When cold air warms up it is capable of holding more water vapour and its relative humidity decreases. The warm dry air will take up water from the surrounding environment and dry everything in sight. The Indians in the Rocky Mountain region call the dry mountain wind "the Chinook", or snow-eater, because of the rapid disappearance or vaporization of the snow in its path.

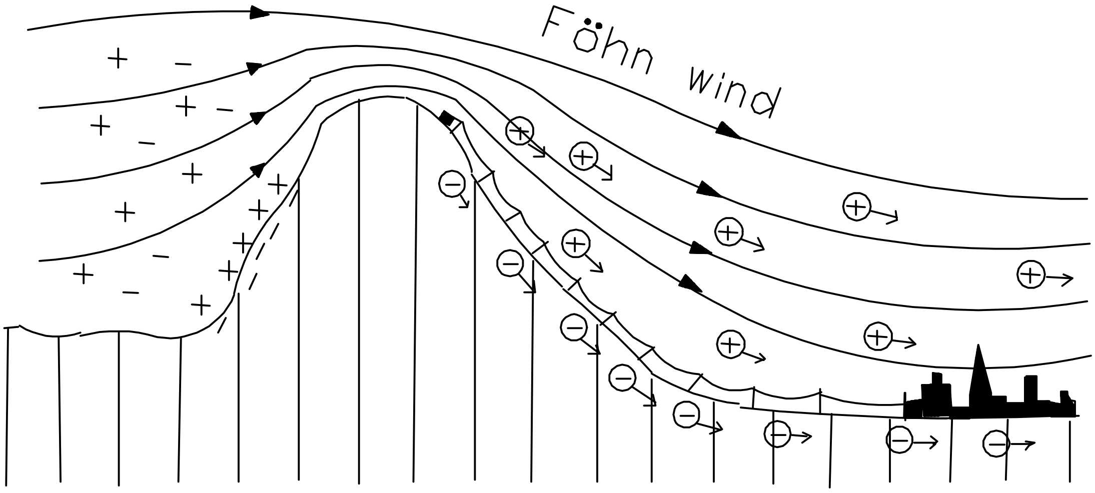

Fig. 41 Dry mountain winds (föhn or Chinook) and positive ions.

The high positive ion concentration can be explained by the fact that winds ventilating the other side of the mountain loose negative ions which are depleted by the electrochemical effect while the excess inert positive ions will follow the air stream over the top, see the diagram in Fig. 41. As the positive space charge moves down the mountain side it is followed by an induced negative image charge along the earth's surface. The induced negative charge is particularly noticeable on telegraph lines going up and down the mountain side. A protruding telegraph line will carry induced negative charge down the mountain which is registered as an electric current in the line flowing up the mountain.

5.4 THE ELECTRODE EFFECT

The electrostatic fairweather field near the earth's surface exhibits some very peculiar variations ascribed the so called electrode effect.

For example, the electric fairweather field can be slightly higher just a few metres above the earth's surface than at the earth's surface itself. This is due to a sudden increase of negative ions in a thin layer above the earth's surface. From Fig. 12, section 2.2, it was explained that the fairweather field can be thought of as electric field lines which connect the excess positive ion population in the atmosphere with trapped negative charges on the earth's surface. If, however, a cloud of negative ions was suddenly formed near the earth's surface it would mean that some of the field lines in Fig. 12 do not reach ground but will terminate on those negative ions. The number of field lines per unit surface area would, therefore, be less at

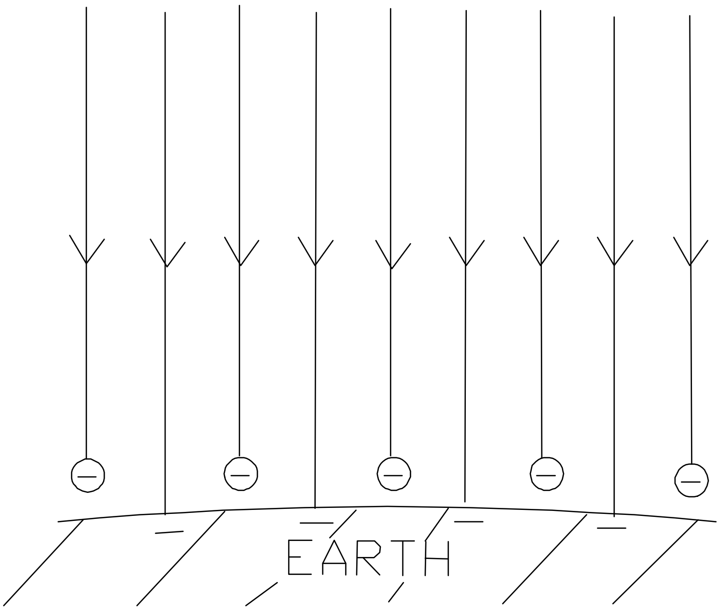

Fig. 42 The electrode effect.

the surface and higher just above the thin negative ion cloud see Fig. 42. A sudden increase in negative ion concentration near the earth's surface could be caused by the passage of a cloud above with a strong positive charge centre. The passage of a positive charge above would temporarily force positive ions to the earth's surface leaving an excess of negative ions behind in a thin layer above ground. The reverse effect is also possible when a negative charge centre passes overhead in which case there is a considerably stronger than normal electric field very near the earth's surface. It is also believed that an electrode effect exists even in the absence of clouds. The idea is that, since positive ions congregate towards the earth's surface because of the normal fairweather field and since there is no supply of negative ions leaving the surface, an imbalance must occur with a higher than normal positive ion concentration near the earth's surface. Numerous measurements, however, do not clearly show such an effect.

5.5 INTERPLANETARY STATIC ELECTRICITY

That static electricity is present on other planets has been established by instrumentation carried on board unmanned space probes. For example, lightning discharges have been observed on Jupiter by the Voyager spacecraft (Smith et al, 1979, Cook et al, 1979 and Gurnett et al, 1979). There is also a strong belief that lightning might occur on Venus.

The rate of current carried by cosmic ray particles to the earth is about 0.2 amperes. This means that the earth will charge 280 volts per second positively unless there is a flow of electrons to the earth at the same rate. The electrons might come from the sun, in which case the sun must charge positively. The existence of strong electrostatic fields in interplanetary space is an untouched field of research. There are problems with orbiting spacecraft building up electrostatic charges which can have adverse effects on measuring instruments and data collected. Extreme charging might occur on space vehicles when returning to earth through the highly ionized layers of the ionosphere. The ventilation of ionospheric ions in combination with the electrochemical charging effect might cause the plasma discharge observed during re-entry, This makes radio communication to from the space vehicles impossible.

CHAPTER 6

INSTRUMENTATION AND MEASUREMENTS

6.1 MEASUREMENTS

Atmospheric electricity is a field that is very easy to get into because it does not require a large capital investment for measuring equipment. It is a difficult field, however, when it comes to the understanding and interpretation of the various measurements. For example, despite vast data collected over two centuries, there is still no agreement on how thunderclouds charge or how the earth-atmosphere fairweather field is maintained.

Today's advanced technology offers eloquent and accurate instruments with fast response time. It is now possible to construct simple electrometers and electromagnetic radiation detectors using chip circuitry. Video recording equipment is becoming a household item that also has great potential for lightning research, making it possible to view flights of lightning bolts in micro-second intervals.

6.2 ELECTRIC FIELD MEASUREMENTS

Most common are measurements of the electric field at or near the earth's surface. The potential gradient at the earth's surface varies in many ways but usually averages about +100 volts per metre during fine weather in the absence of clouds. Except for the normal diurnal variations of the fairweather field (see sec. 2.2), strong rapid changes are often registered which might be due to electrically charged dust or heavy pollution. Marked changes in the fairweather field have been observed before the onset of fog or during temperature inversions in the lower atmosphere. Many of the above field effects and their causes are still not fully understood. The electric field below thunderclouds are usually very strong and easy to detect. Rapid field changes occur during lightning discharges and field reversals are common. Field measurements below thunderclouds reveal such features as charging rates, electric polarity and discharge rates to mention a few. There are several ways one can measure the electric field in the atmosphere. A simple approach is to connect an electrometer to an antenna of some sort such as shown in Fig. 43. The antenna can be a conducting disc placed at a predetermined height

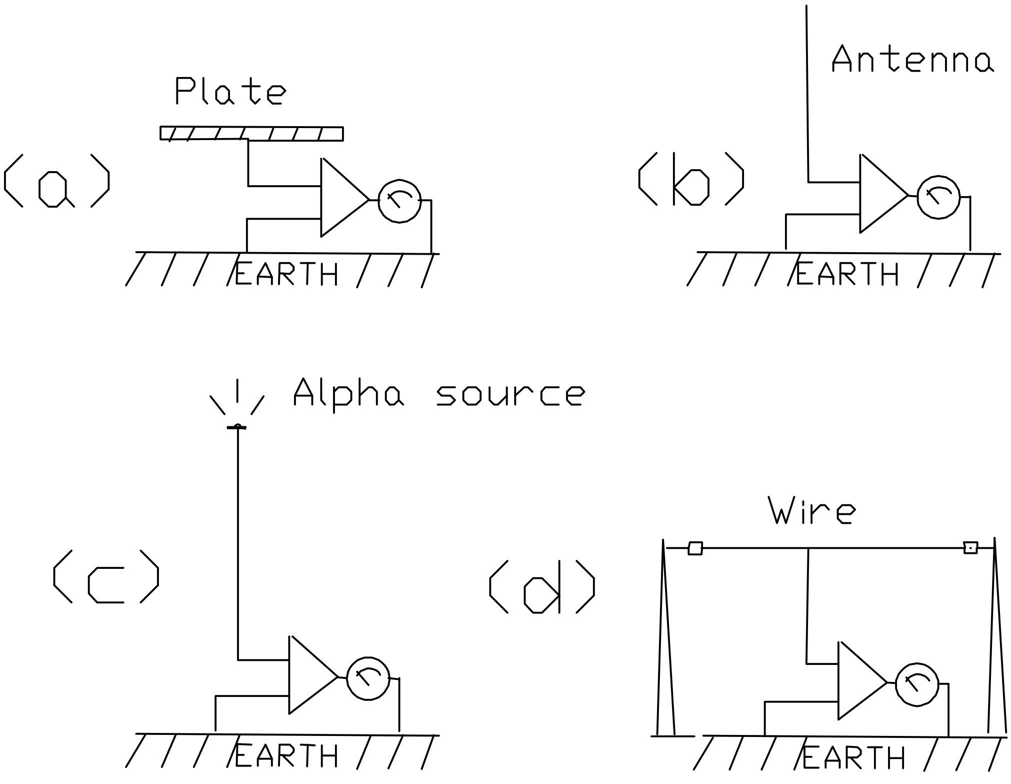

Fig. 43 Different antenna configurations for electric field measurements in the atmosphere. (a) Disc antenna. (b) Whip antenna. (c) Whip antenna with radioactive probe. (d) Long wire antenna.

above ground (Fig. 43a). The disc will charge and reach a potential which is equal to or very near the potential of the atmosphere at that height. The diagram in Fig. 43b shows an electrometer connected to a short whip antenna which gives voltage readings that are difficult to calibrate since the antenna whip will protrude through many levels of electric potential. An ion-producing radioactive alpha source at the tip of the whip antenna, see Fig. 43c, will increase the electric conductivity in the air near the tip and ensure a better accuracy of potential measurement as a function of height. A long wire, suspended above ground at predetermined levels, will give accurate readings of atmospheric potentials as a function of height, see Fig. 43d.

6.3 THE ELECTROMETER

There are many excellent electrometers commercially available, but since the electronic market of today can offer a variety of sophisticated integrated circuits, it makes simple home made devices nearly as

effective. For example, the circuit in Fig. 44 has been used by the author in many experiments including the Gerdien cylinder measurements described in section 2.1. It uses two 9 volt batteries and is portable, which makes it convenient for experiments in the field. The electrometer is mounted in an electrically shielded metal box.

Measuring electric fields and field changes during thunderstorms will produce many interesting results. Lightning discharges cause rapid field changes and polarity reversals which can be registered on a chart recorder. The recovery time of the electric regeneration process in clouds is also a very interesting feature that can be studied with the help of a recorder. During thunderstorm measurements it is recommended that the electrometer in Fig. 44 be fitted with an R C network which increases the time constant of the circuit to several seconds. Because of the strong fields produced by thunderstorms, it is also advisable to decrease the sensitivity of the circuit, by changing R_i and R_f. A typical circuit modification for thunderstorm measurements is shown in Fig. 45.

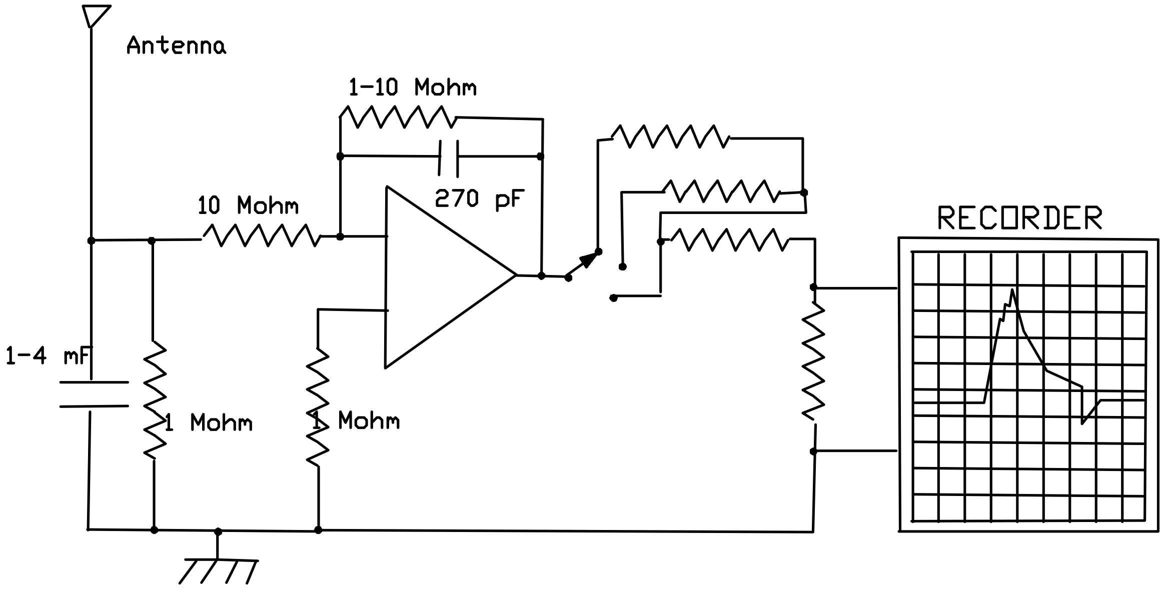

Fig. 45 Circuit for electric field measurements of thunderclouds

6.4 THE FIELD MILL

The electric field mill is a device based on electrostatic induction. It consists of one or two electrodes which either rotate in an electrostatic field or become periodically exposed to a field by rotating vanes. Fig. 46 illustrates a cylindrical field mill which consists of two cylinder halves that are electrically insulated from each other. An electric motor rotates the two halves in the electric field to be measured so that they become alternately exposed to both the positive and negative direction of the field. The result is that an alternating (ac) signal is generated across the two halves which can be easily amplified. The rotating shutter field mill, on the other hand, comprises a stationary electrode, which becomes periodically exposed to the external electric field through a rotating grounded disc (see Fig. 47). A variation on this type of field mill is a stationary grounded cover plate with a rotating

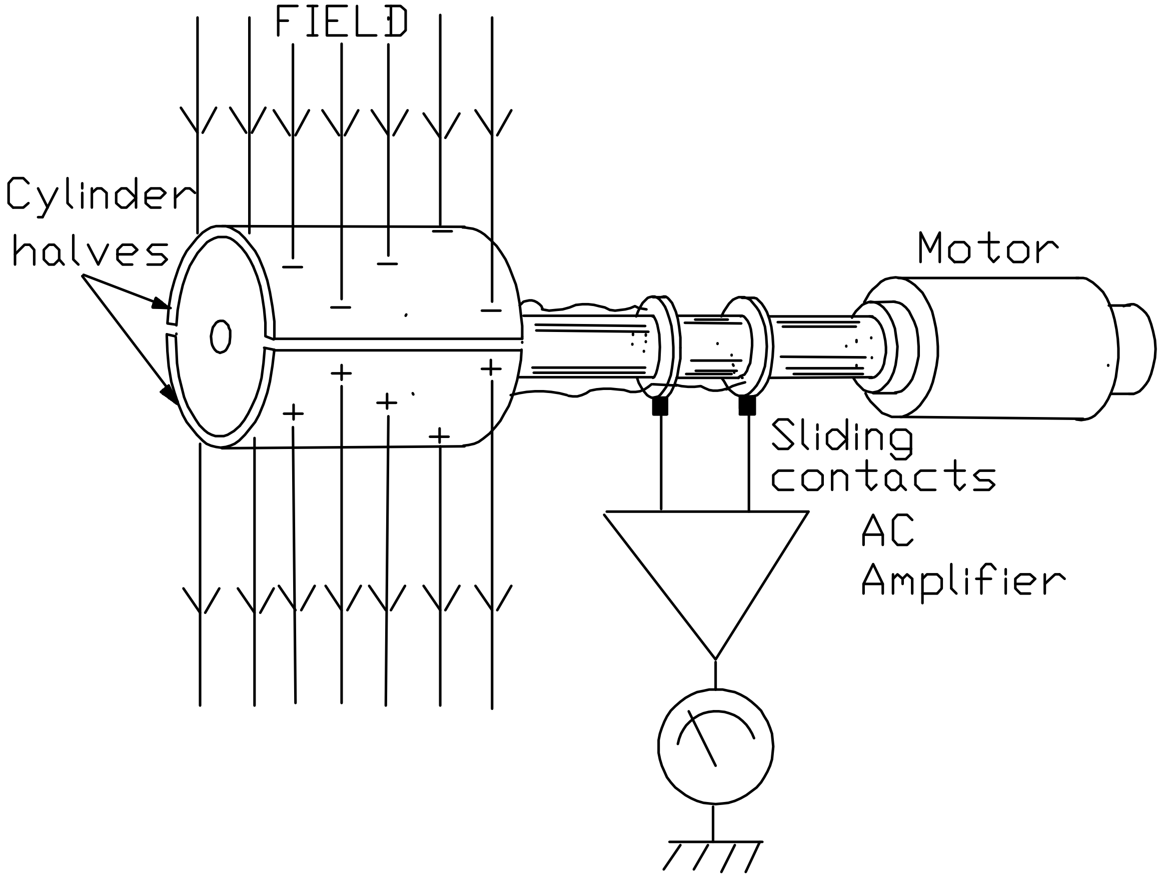

Fig. 46 Cylindrical electric field mill.

disc electrode. Although not commonly used, the cylindrical field mill has the advantage that when mounted in a fixed position it can also indicate the direction of the field. This is accomplished by measuring the phase shift of the ac signal relative to the orientation of electric fields need to be measured. The rotating shutter type field mill has to be pointed towards the source of the field in order to obtain a maximum reading. This feature is useful when searching for static charges that might cause problems in the laboratory or industrial plant. The rotating shutter field mill is commercially available in several countries.

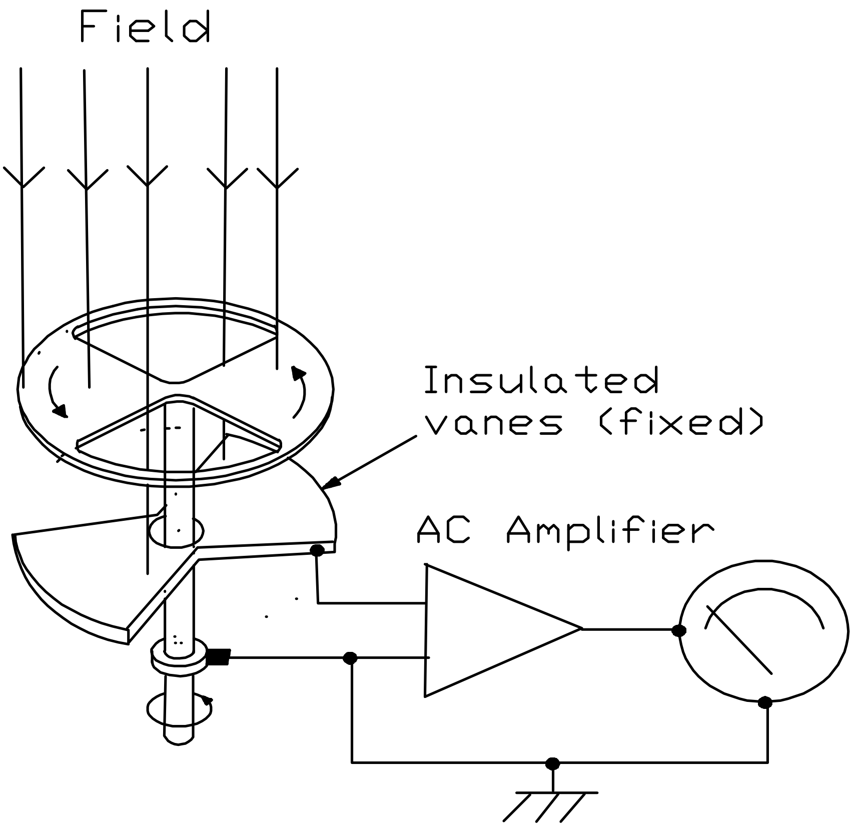

Fig. 47 Rotating shutter electric field mill.

6.5 ELECTROMAGNETIC DETECTION

The crackling sound of atmospherics generated by lightning is familiar to everyone who listens to radio. "Sferics" interference is usually stronger in the low frequency band (10 - 500 kHz) were the electromagnetic energy spectrum of lightning is most powerful. There is also an interest in the higher frequency bands of lightning radiation, around 10 - 30 MHz, relating to corona discharges and fast field changes. An attractive feature of atmospherics is that it enables long distance detection of lightning storms. Radio receivers with directional antennae are used to determine the position and movement of thunderstorms. Several stations can accurately pin-point storms by triangulation. Loop or frame antennae, such as seen on ships, are used and a typical electric block diagram is shown in Fig. 48. Experience has shown that the shape of electromagnetic pulses received from lightning changes with distance, which makes it possible to estimate the distance from the antenna to the discharge. Some aircraft are fitted with "stormscopes" utilizing the above principles to determine the direction and distance of nearby intracloud discharges in order to avoid dangerous confrontation with lightning. Radar echoes of lightning bolts can be seen as reflections superimposed on echoes of heavy precipitation in clouds. It is believed that the ionized channel, produced by lightning, is large enough to cause reflection of radio waves. Radar observations of antenna for

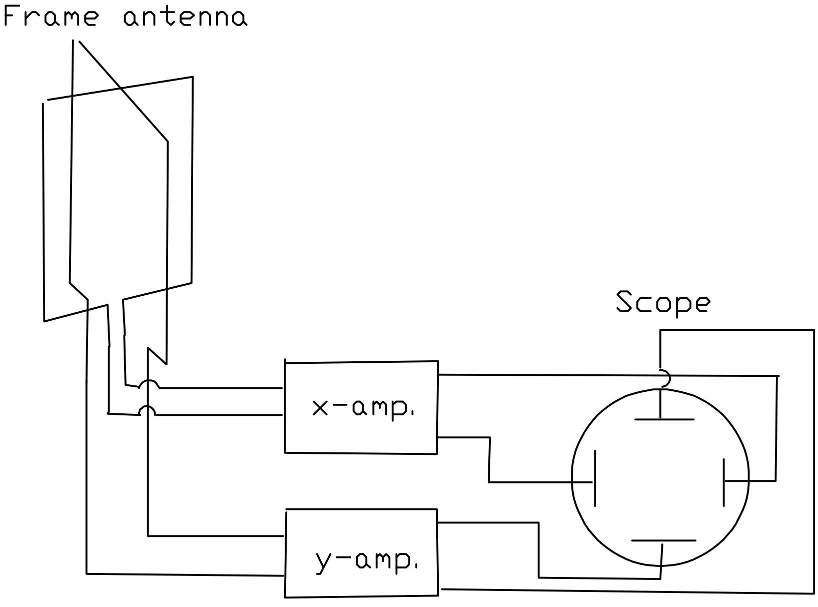

Fig. 48 Loop or frame lightning detection.

thunderstorms bring out many interesting features which might aid in the understanding of the physical processes at work in clouds. For example, radar reflections from precipitation appear several minutes before any visible electrical activity. The radar reflections rise at first together with the cloud top but start to descend as soon as lightning occurs. At the same time lightning commences, precipitation becomes visible and starts to fall out of the cloud. One question often asked is whether lightning induces gushes of precipitation; or vice versa.

6.6 THE FUTURE

There are still many problems outstanding in the field of atmospheric electrostatics. New and better measuring devices will help solve some of the problems still at large, but equally important is the development of new ideas and techniques.

Electrostatic fields and ions in the atmosphere and their effect on our well being is still an open question. There are no conclusive results yet available and more research is needed. It is known, however, that both positive and negative ions reduce the life of bacteria (Serratia marsescens) residing in aerosols and that high negative ion concentrations seem to offer relief to persons suffering from bronchial disorders.

Static electricity in the atmosphere might not offer much practical value but it has intrigued many of the best theoreticians and experimentalists throughout time. There is no shortage of thunderstorms and lightning but the problem is how to safely penetrate a cloud and study its micro structure. One alternative is to use large cloud chambers capable of producing convective clouds. Some of the problems might be solved with the aid of orbiting space laboratories or unmanned satellites. The world wide thunderstorm activity and lightning distribution can be monitored from space and correlated with electric field measurements at earth. This could help

DESIGNING A DX CRYSTAL SET

by Mike Tuggle
46-469 Kuneki St.
Kaneohe, HI 96744-3536
E-Mail: tuggle@apacs.com

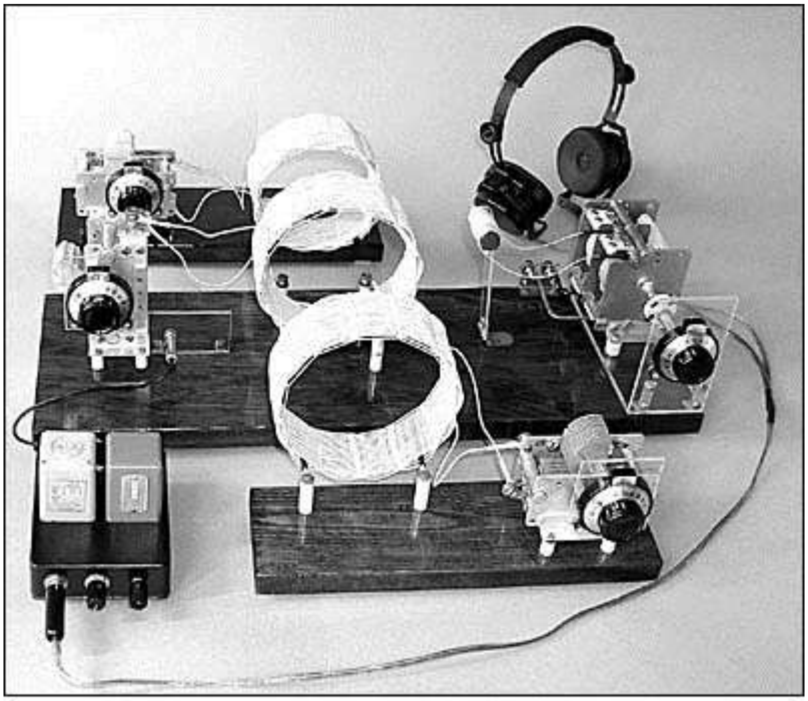

Fig. 1. The 'Lyonodyne-17,' an example of a well-designed DX crystal set.

Long distance reception with crystal radios is once again becoming a serious pursuit among hams and other radio hobbyists. They are discovering that the DX capabilities of these receivers have been greatly underrated. I've been particularly interested in crystal sets since 1959, when I first discovered you could actually DX with them. The Internet has aided crystal set DX activity by making exchange of ideas between like-minded enthusiasts much, much easier. This article only touches the surface from a personal perspective. The reader is encouraged to pursue the online resources, described below, covering all aspects and providing further examples of this fascinating hobby.

In this article I'll cover general design considerations for building DX crystal sets, but will leave the actual construction specifications up to you.

Equipment

Figures 1 and 2 show an example of a DX crystal set. I call it the "Lyonodyne-17." The design evolved from an earlier version described in the November, 1978 OTB. As you can see, this is not your grandfather's crystal set.

Antenna (right) and detector (left) tuners are mounted on the middle board. Wave traps are located fore and aft on separate boards, making it possible to adjust the coupling by moving the boards. The antenna coil (L1) is wound on a short ferrite rod. The matching transformer unit for my RCA "Big Cans" sound powered phones is at front, left.

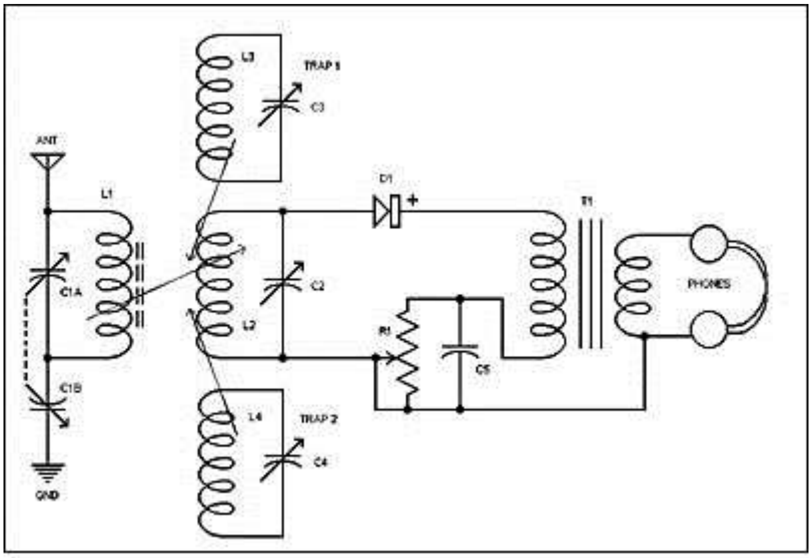

Fig. 2. Schematic of the 'Lyonodyne-17.'

So, what makes a crystal radio a "DX" set? Well, this one is double-tuned (L1-C1 and L2-C2) for selectivity to tune weak DX stations in the RF jungle we now live in. Some DX sets resort to triple tuning for even more selectivity -- depends on how many hands you have to do the tuning. The wavetraps (L3-C3 and L4-C4) can be tuned to reject strong unwanted stations in the manner of the notch filter on a communications receiver.

Coils L2 through L4 are basket-wound litz wire for low loss and high Q. Variable capacitors C1 through C4 are highest-quality, silver-plated, ceramic-insulated units--as perhaps only the military could specify. All these components are isolated from the mounting board by ceramic standoff insulators. Overkill maybe, but why take chances?

Design Principles

Two fundamental principles underlie DX crystal set design and construction: use of low-loss components and proper impedance matching between stages.

Avoid the temptation to construct the set with vintage components. The result may be a handsome set that is only a fair performer. I have such sets, and they sit up on the shelf and look nice. However, for ultimate performance, one should rely on top quality (usually modern) components and materials.

This is especially important for tuning capacitors, coil wire and forms, and detector diodes. Layout and construction, particularly in the RF-carrying sections (antenna through detector), should follow good HF practices: short direct leads, careful insulation of components, and avoidance of switches, taps and other trappings in the 'hot', RF-carrying sections.

The crystal set, like any other radio, consists of a series of stages--each with a function, each coupled to the next. The stages of a simplified crystal receiver are diagrammed in Figure 3. The resistances shown are used for detailed circuit analysis that will not discussed here.

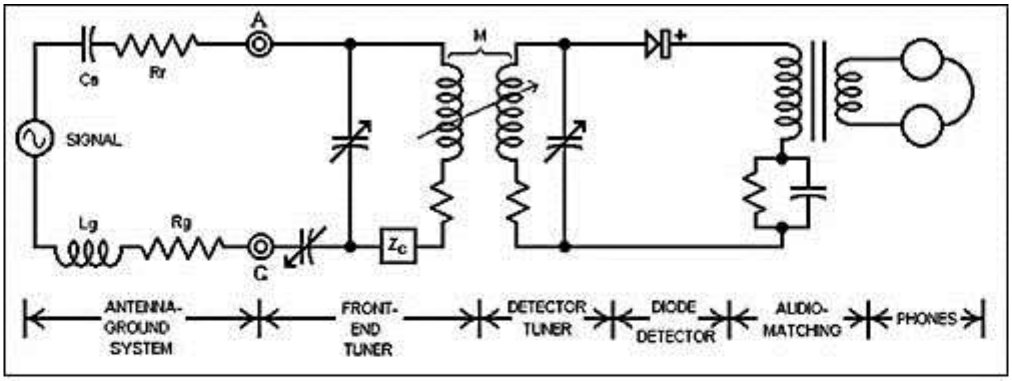

Fig. 3. The stages of a typical DX crystal set (see text).

We have, from left to right: antenna-ground system, front-end (antenna) tuner, secondary (detector) tuner, diode detector, audio matching and finally, phones. Maximum transfer of available signal power from one stage to the next happens when the impedances of these stages are matched to each other--from antenna to phones--and indeed, from phones to one's ears.

Components

A good outside antenna-ground system is essential for DXing. Loop antennas do not have enough pickup to be effective. An inverted L longwire 20 to 30 feet high and 50 feet long is a good start. The one truth to antenna design is, "higher is better." Any effort expended to raise the antenna, even a few feet, will be amply rewarded. In the most recent crystal set DX contest a third design principle emerged: A huge antenna can overcome shortcomings in the first two principles. The winner suspended 140 feet of litz wire near vertically using helium-filled balloons. Another high-scorer just happened to have a 140-foot tall base-insulated tower and four 1000-foot Beverage antennas to complement his junk box set. Most of us have neither the real estate nor the rigging capability to put up one of these 'mega' antennas. So it behooves us to heed principles 1 and 2.

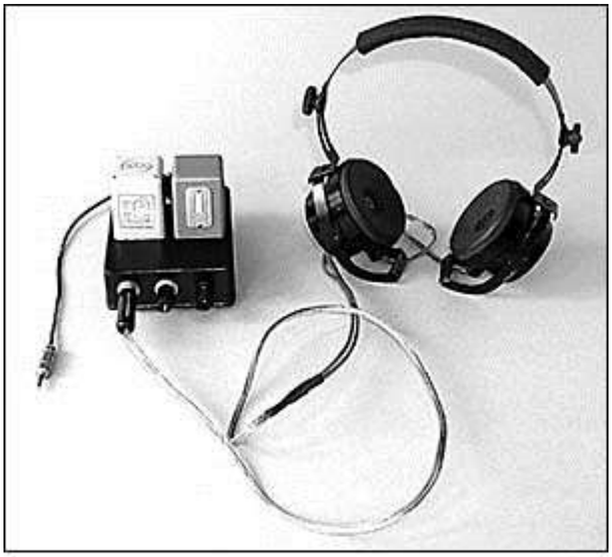

Fig. 4. RCA balanced-armature phones, with matching transformer.

The front-end (antenna tuner) design shown here is one of several that can be used. This particular design tunes a wide variety of antenna-ground systems. Other DX crystal sets use a simple series tuning circuit effectively--especially on long antennas.

The diode detector provokes more mystery, controversy and debate than any other component. Some folks favor low-resistance germanium diodes like the 1N34A or rock stands with galenas. Others swear by high-tech Schottky diodes. The emerging truth is, there is no universally perfect diode.

The 'best' diode depends specifically

upon the set it is used in. Per the second principle, the diode needs to match the tank circuit feeding it and the transformer and phones that it feeds. With some care, a high-Q tank with litz wire coil and a modern, military-grade variable capacitor can attain a resistance of from several hundred kilohms up to a megohm. Only Schottky diodes and a few modern germanium diodes have resistances this high. The old catswhisker-rock stand detectors have far lower resistances.

The most practical approach to selecting the right diode is to apply an A-B listening test to a number of them. Two diodes are mounted in a test stand arranged to quickly switch between them. Using a fairly weak station, one can test a pile of diodes, pair-wise, keeping the winner after each test, until the ultimate one is found. But it's most important to realize that this diode is 'best' for the particular set it was tested in. It may be a quite poor performer in a different set.

Surplus, sound-powered (more properly, balanced-armature) phones have become the industry standard for DX crystal sets. Baldwin Type C's were an early example. Now, post-WWII surplus units made by RCA and US Instruments Corp. (USI) are preferred.

These phones are low impedance and must be matched to the high-impedance tank (L2-C2) and detector diode by an audio transformer having, typically, 50- to 600-ohm and 50- or 100-kilohm windings (Figure 4). The quality of the transformer is very important, so that its insertion loss is small. UTC input transformers have a good reputation for low loss. The final touch is a comfortable set of headphone cushions for good acoustical coupling to the ears and exclusion of outside noise.

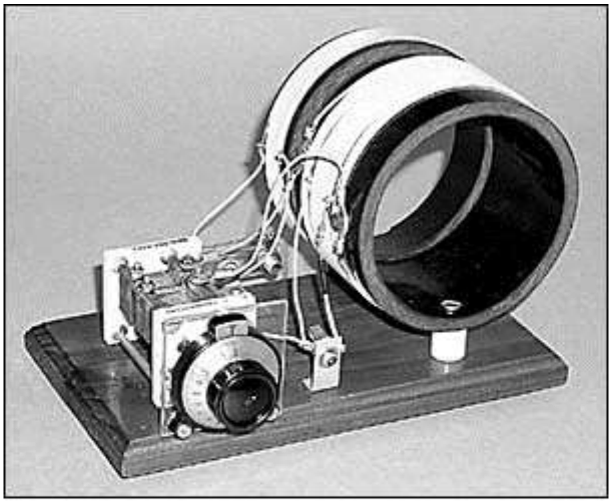

Fig. 5. A '12,000-mile' short-wave receiver.

DX Experiences

Under favorable conditions, medium wave or broadcast band DX crystal sets can receive hundreds of stations--some of them thousands of miles distant. In fact, DX crystal set performance is comparable to any other radio (powered or not) short of a full-blown communications receiver with its own outside antenna. The rule of thumb is, if you can hear them on a radio, you can hear them on a crystal set.

The best times to listen are at sunrise and sunset, when stations are signing on or off, raising or dropping their powers, and changing their antenna patterns. These circumstances make for a jumble of regional stations ripe for the picking. Deep night is usually the best time for flat-out DX.

In 15-year stints at two locations in Maryland, I accumulated logs of over 600 and 400 stations, respectively. The most distant receptions, at 1800 to 2200 miles, were a few powerful stations in the Caribbean area and adjacent South America. I was aided, no doubt, by the largely water path between them and me. The farthest overland station was in Denver at about 1500 miles.

When I moved to Hawaii, I wasn't sure what to expect. The local Honolulu stations were givens. But what about the outer islands? And all-importantly the next stations, mainlanders, the closest some 2400 miles away? As it turns out, Hawaii is an ideal DX location--for distance if not for sheer numbers of stations. With no regional stations, sunrise-sunset activity is non-existent.

West coast 500-watt stations, 2500 miles distant, have been heard here. High-power stations in Cuba (4800 mi.) and the Caicos Islands (5500 mi.) have also been heard, thanks to a mostly water path. Stations from the "interior" also make it over. Last year, it was neat to hear KRVN in snowbound Nebraska (3600 mi.) using a homemade cat's whisker mineral detector. This must be what it was like in the old days.

With low station powers and crowding, medium-wave broadcast band DXing represents the greatest challenge. On short wave there's no limit to the distance--reception is truly worldwide. I occasionally hear the South African broadcasts nearly 12,000 miles away; Johannesburg and Hawaii are nearly at antipodes. From the mainland, Australia (11,000 miles) was a routine catch. Figures 5 and 6 show my "12,000-mile" crystal set.

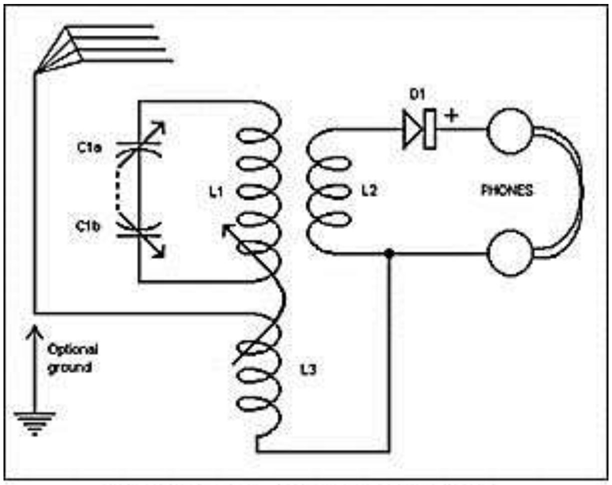

Fig. 6. Schematic of the '12,000 mile-er.'

Crystal Set DX Activities

Crystal set DX activities include discussion forums sharing ideas and results, an annual DX listening contest now into its sixth year, and the occasional set-building contest where some remarkably high-caliber craftsmanship comes to the fore. All of these activities are served up on the Internet.

The following site is a highly recommended grand portal to the wonderful world of crystal set DXing: Owen Pool's Crystal Radio Resources at http://www.thebest.net/wuggy. The comprehensive set of links here covers all aspects of the hobby. This site is headquarters for the annual crystal set DX (XSDX) contests open to everyone. The contest usually takes place in late January. Watch for announcement of specific dates and rules.

My own experiences over the years have led me to shed my skepticism of the incredible DX reports made by old-timers back in the early days. Component technology was not what it is today, but circuit technology was, and the sparsely populated bands back then had to be a lot more DX-friendly. You may want to pull an antique crystal set off the shelf and give it a spin. I'd encourage it.

Some of these old sets are extremely well built. The construction of the military BC-14A/SCR-65 never ceases to amaze me--and others were built just as well. But to start out, I'd recommend conceding to modern technology by using a good, modern diode and sound-powered phones with matching transformer. With just a little luck, prepare to be amazed all over again!

UNITED STATES PATENT OFFICE.

ROBERT VOSS, OF BERLIN, GERMANY, ASSIGNOR TO JAMES W. QUEEN & CO., OF PHILADELPHIA, PENNSYLVANIA.

INFLUENCE-MACHINE.

SPECIFICATION forming part of Letters Patent No. 410,053, dated August 27, 1889.

Application filed January 21, 1889. Serial No. 297,066. (No model.)

To all whom it may concern:

Be it known that I, ROBERT VOSS, a subject of the King of Prussia, German Emperor, residing at the city of Berlin, in the Kingdom of Prussia, German Empire, have invented certain new and useful Improvements in Influence-Machines; and I do hereby declare that the following is a full, clear, and exact description of the invention, which will enable others skilled in the art to which it appertains to make and use the same.

My invention has reference to improvements in double-acting electrical influence-machines; and it consists in an arrangement of three circular glass disks, two of which are rotary and on the same axis, one of these receiving any electricity that may escape on its side from the fixed or third disk and also generating electricity by friction with the air.

It also consists in certain details of construction hereinafter described, and particularly pointed out in the claims which follow this specification.

I carry out my invention in the way shown in the accompanying drawings, in which—

Figures 1 and 2 are respectively front and top views of a machine provided with my improvements.

Similar letters of reference indicate like parts in both of the figures.

A is a fixed glass disk having on it two paper sectors *s s*, placed diametrically opposite each other.

B and C are the two rotary glass disks, B being set out at equal distances from its center with small metal knobs *b b*, which, in conjunction with small metal brushes *c c*, serve to generate the electricity to be originally communicated to the influence-machine.

d d are metallic points serving as conductors.

k k are electrodes, which are for the purpose of producing a continuous spark, and they are in communication with two Leyden jars *l l*. I provide either one or both of these electrodes *k k* with a flat circular or disk-like attachment *k'* of insulating material, as rosin, gum, or hard rubber, which is secured to the metal electrode by a central stem, as shown, leaving an air-space between the two parts. With such a surface having this air-space between it and the metal electrode I obtain marked efficiency in the dispersion of the spark and avoid the troublesome brush-discharge.

Underneath the base-plate H is an arrangement by which the two Leyden jars *l l* may be placed in electric communication with each other. It consists of a metal bar *m*, turning on a point *o*, and of the metal wires *n n*, each connected to one of the Leyden jars. The bar *m*, as shown in the drawings, may effect a connection between the two wires *n n*, which may again be disconnected by turning the bar *m* on point *o*. The disk C is uncovered and serves for the reception of any electricity escaping on the rear side from the disk A, and also for generating a small quantity of electricity by its friction with the air when in rotation. This central disk A, being stationary and located in close proximity to the rotary disk on either side, acts after the manner of a plate in a condenser, tending to hold the electricity bound on both surfaces. The electricity thus held in tension appears to react upon the rotary plates to give increased effect. The two disks B C are mounted on one common axis D, receiving rotary motion from the crank K.

I am aware that for a long time past influence-machines have been produced having for their object to obtain by influence a larger quantity of electricity than that obtainable with the Holz machine. While this latter consisted mainly of a pair of circular varnished glass disks, one fixed and the other rotating, the improved construction had a number of such pairs of glass disks. By this arrangement the machine was very large and expensive.

By my machine a relatively larger quantity of electricity is obtained in a very simple way by influence through the back second wholly uncovered disk serving both as a protecting-body against any escape of electricity and as a generator of electricity by reason of its generating a small quantity of electricity by friction when rotating with the air present between it and the fixed disk, such electricity being then re-enforced by influence.

I am aware that influence-machines have

been constructed in which two rotary disks are adapted to rotate on opposite sides of two centrally-located fixed disks, said fixed disks having space between them. In this construction, however, of two fixed disks the space between said fixed disks is not utilized, and much of the influence of the intervening bound of electricity is lost. I therefore do not claim a double arrangement of such mechanism collectively; but

What I do claim as my invention, and desire to secure by Letters Patent, is—

1. In an influence-machine, the combination of a central fixed disk and two rotary disks attached to a shaft extending through the fixed disk, with two electrodes, one of which consists of a non-conducting surface attached to a conducting-surface, but separated therefrom by an air-space, the other electrode being of usual form, and both electrically connected to the influence-machine, substantially as described.

2. In an influence-machine, an electrode consisting of a non-conducting surface attached to the conducting-electrode, said parts being separated by an air-space, substantially as shown and described.

3. An electrode for an influence-machine, consisting of a flat or disk-like conductor, in combination with a flat or disk-like conducting-surface connected to the conducting part by a central stem, as shown and described.

In testimony whereof I signed this specification in the presence of two subscribing witnesses.

ROBERT VOSS.

SELF-EXCITED VARIABLE CAPACITANCE ELECTROSTATIC GENERATOR

Charles H. Goldie, Bedford, Mass., assignor to High Voltage Engineering Corporation, Burlington, Mass., a corporation of Massachusetts

Filed May 31, 1960, Ser. No. 32,821
4 Claims. (Cl. 322—2)

This invention relates to electrostatic generators wherein the charge transfer mechanism makes use of capacitive effects between charged bodies and electrodes upon which charge is to be induced, and in particular to the self-excitation of such generators.

The invention may best be understood from the following detailed description thereof, having reference to the accompanying drawings in which:

FIG. 1 is a diagram illustrating one form of a variable-capacitance electrostatic generator;

FIG. 2 is another diagram further illustrating the arrangement of FIG. 1;

FIG. 3 is a diagram illustrating a modification of the apparatus of FIG. 1 and embodying the invention; and

FIG. 4 is a diagram illustrating a portion of the apparatus of FIG. 3.

Referring to FIG. 1 of the drawings, therein is shown a rotor **1** and a stator **2**. The rotor **1** has a charge thereon and in FIG. 1, it is charged positively. A power supply **3** is indicated for maintaining the charge on the rotor **1**.

Referring now to FIG. 2, it will be seen that the stator **2** is connected to ground by a resistive path **4** which is connected in parallel with at least one rectifier **5** so that current can flow in only one direction between the stator **2** and ground.

In the device shown in FIGS. 3 and 4 the rotor serves as a capacitive link between a stationary charging electrode and a stator. Referring thereto, a rotor **11** periodically passes close to a stator **12**. However, instead of carrying its own charge as in the device of FIGS. 1 and 2, the necessary inducing charge on the rotor **11** is itself induced on the rotor **11** by the charging electrode **13**. Thus when one end of the rotor **11** is in the vicinity of the stator element **12** and the opposite end of the rotor element **11** is in the close vicinity of the charging electrode **13**, a negative charge is induced on that portion of the rotor **11** which is near the charging electrode **13** with the result that positive charge appears at the opposite end of the rotor **11** since the rotor **11** must itself be electrically neutral.

The invention will now be described with reference to the apparatus shown in FIGS. 3 and 4, but it will be clear from the foregoing that the invention could equally well be used with a device of the type shown in FIGS. 1 and 2. The principal advantage of the device shown in FIGS. 3 and 4 is the fact that it eliminates the necessity for a brush on the rotor to supply charge thereto, since the charge on the rotor is induced capacitively.

Referring back briefly to FIGS. 1 and 2, it will be recalled that the invention is concerned with the construction of a self-excited generator with no external energy other than shaft power supplied. That is to say, the objective is a completely self-charging generator. Referring to FIGS. 1 and 2, it will be seen that direct feedback of the output to the induction plate is ruled out by the polarity switch inherent in this type of machine. The difficulty is avoided by the two section unit shown in FIGS. 3 and 4. Here a fraction of the output voltage of each section is fed to the induction plate of the other.

The action of the circuit is best understood by looking first at the lower section only. The rotor **11** is an electrically isolated flat fan-like rotor mounted on an insulating shaft **14** driven by an appropriate motor or other prime mover **15**. As it rotates, the rotor **11** periodically covers the stator **2** and the charging electrode **13**, which are each insulated and sector-shaped. The charging electrode **13** is maintained at a positive D.C. potential with respect to ground. As the rotor **11** rotates into a position covering the charging electrode **13** and the stator **12**, the capacitance between the charging electrode **13** and the stator **12** increases and negative charge is induced from ground through a rectifier **16** to the stator **12**. As the rotor **11** uncovers the stator **12** and the charging electrode **13**, the capacitance decreases and the stator **12** rises in potential negative with respect to ground. The rectifier **16** blocks any flow of negative charge from the stator **12** and as the negative potential of the stator **12** rises, current flows through a second rectifier **17** to the load **18**. A fraction V2 of this negative load voltage is applied to the charging electrode or induction plate **13'** of the second or upper section by means of the potentiometer **19**. The charging action in this second section is identical to that in the first section except for reversed polarities and the output of the second section is correspondingly fed-back to the first section induction plate **13** via a second potentiometer **20**. The variable resistors of the potentiometers **19**, **20** control the output voltage and power by adjusting the feedback ratios.

The circuit is regenerative; it remains only to supply a small reference voltage to start in the right direction. The use of stator and rotor materials with suitable contact potentials is one solution to this; a small battery **21**, which might be, for example, of the nuclear type, in one induction line as shown is another solution. Suitable voltage limiting devices such as corona tubes **22** would be added either across the induction plate **13** or, as shown in FIG. 3, across the load **18** as checks to prevent excessive voltage build-up.

A number of features inherent with this circuit are of interest.

The usual slip rings and brushes are eliminated by the use of the stator **12** and the charging electrode **13**, and an isolated rotor **11** rather than a single stator **2** and a rotor **1** maintained at constant induction potential as shown in FIGS. 1 and 2.

In spite of the fact that the second section was added for the purpose of self-excitation, both output voltages are added together across the load **18**, **18'**. The arrangement pictured is merely for explanation of the self-excitation principle. The ground shown, for example, is not required; and for higher voltages, the units may be cascaded with a common insulating drive shaft **14**. For a given total voltage output, the number of rotor stator sets is the same for this self-charge generator as for a generator requiring auxiliary charging supplies.

Two poles are shown for simplicity; in an actual machine a greater number would be more practical. The system also applies equally well to other geometrical arrangements, such as the concentric or segmented drum design mentioned in U.S. Patent Application Serial No. 829,823.

Having thus described the principles of the invention, together with an illustrative embodiment thereof, it is to be understood that, although specific terms are employed, they are used in a generic and descriptive sense and not for purposes of limitation, the scope of the invention being set forth in the following claims.

I claim:

1. A self-excited variable-capacitance D.-C. generator comprising in combination a first and a second electrode, a third and a fourth electrode capacitively coupled to said first and second electrodes respectively, means for vary-

ing the capacitance between said first and third electrodes and between said second and fourth electrodes, a first rectification means between said third and fourth electrodes, a load one end of which is connected to said third electrode through a second rectification means and the other end of which is connected to said fourth electrode through a third rectification means, said rectification means being thus connected in series and with the same orientation, and means for utilizing a portion of the voltage across said load to charge said first and second electrodes in mutually opposite senses.

2. A self-excited variable-capacitance D.-C. generator comprising in combination a first and a second rotor, a first and a second stator capacitively coupled to said first and second rotor respectively, means for rotating said rotors so as to vary the capacitance between said first rotor and said first stator and between said second rotor and said second stator, a first rectification means between said stators, a load one end of which is connected to said first stator through a second rectification means and the other end of which is connected to said second stator through a third rectification means, said rectification means being thus connected in series and with the same orientation, and means for utilizing a portion of the voltage across said load to charge said rotors in mutually opposite senses.

3. A self-excited variable-capacitance D.-C. generator comprising in combination a first and a second charging electrode, a first and a second stator, a first rotor capacitively coupling said first charging electrode and said first stator, a second rotor capacitively coupling said second charging electrode and said second stator, means for rotating said rotors so as to vary the capacitance between said charging electrodes and said stators, a first rectification means between said stators, a load one end of which is connected to said first stator through a second rectification means and the other end of which is connected to said second stator through a third rectification means, said rectification means being thus connected in series and with the same orientation, and means for utilizing a portion of the voltage across said load to charge said charging electrodes in mutually opposite senses.

4. A self-excited variable-capacitance D.-C. generator comprising in combination a first and a second charging electrode, a first and a second stator, a first rotor capacitively coupling said first charging electrode and said first stator, a second rotor capacitively coupling said second charging electrode and said second stator, means for rotating said rotors so as to vary the capacitance between said charging electrodes and said stators, a first rectification means between said stators, a load one end of which is connected to said first stator through a second rectification means and the other end of which is connected to said second stator through a third rectification means, said rectification means being thus connected in series and with the same orientation, means for utilizing a portion of the voltage across said load to charge said charging electrodes in mutually opposite senses, and voltage limiting means across said load.

[57] **ABSTRACT**

Two inversely ganged variable capacitors having a common movable element varying the capacities such that when one capacitor is at maximum capacitance, the other is at minimum capacitance, have, after initially charging, a substantially constant contained or trapped charge distributed between the two capacitors. As the capacities of the capacitors are varied, a potential difference is developed between the fixed plate of one capacitor and the fixed plate of the other. When these two potential points are connected to a load, charge is transferred from one capacitor to the other as a current flow through the load. The total charge is not diminished, the energy supplied the load being the energy expanded on moving the movable charged plates. As the movable plates are moved in a cyclic manner an alternating current is provided to the load.

THE INVENTION

ELECTROSTATIC ENERGY CONVERSION SYSTEM

RIGHTS OF THE GOVERNMENT

The invention described herein may be manufactured and used by or for the Government of the United States for all governmental purposes without the payment of any royalty.

BACKGROUND OF THE INVENTION

The field of the invention is in electrostatic machines.

Electrostatic machines have been well known for many years. The Toepler-Holtz and the Wimshurst machines were early electrostatic generators. Now their usage is mainly for demonstrations in the Physics Laboratory. The only remaining electrostatic machine to remain in extensive usage is the Van de Graaff type electrostatic generator. It is presently used to generate extremely high voltage potentials for atomic research. Substantially all of the prior art devices are direct current type machines.

The following publications may be helpful in further understanding the art. Electrostatic Sources of Electric Power, John G. Trump, Electrical Engineering, Vol. 66, No. 6, June 1947, pages 525-534; U.S. Pat. No. 2,810,878 to patentee N. Felici, and U.S. Pat. No. 3,094,653 to patentees D. B. LeMay et al.

SUMMARY OF THE INVENTION

An ac electrostatic variable capacity energy conversion system utilizing a fixed contained charge functions as an electrical generator when mechanically driven or as a motor providing mechanical shaft power when electrically driven.

BRIEF DESCRIPTION OF THE DRAWING

FIG. 1 is a simplified pictorial-schematic diagram representative of a rotational generator embodiment of the invention;

FIG. 2 is a simplified pictorial schematic diagram representative of a reciprocally driven generator embodiment of the invention;

FIG. 3 is an electrical schematic diagram of the embodiment illustrated in FIG. 2;

FIG. 4 is a schematic diagram illustrative of the electrical charges and capacitances of the embodiment physically illustrated in FIG. 1;

FIG. 5 is a pictorial-schematic representation of an embodiment of the invention wherein the load is between dielectric materials;

FIG. 6 is a schematic diagram of the system shown in FIG. 5 illustrative of the charges and capacitances;

FIG. 7 is a schematic diagram of a pulsed energy input embodiment of the invention in State A;

FIG. 8 is the same embodiment except in State B;

FIG. 9 is the same embodiment except in State C;

FIG. 10 is the same embodiment except in State D;

FIG. 11 is a schematic representation of an embodiment of the invention having pulsed energy input with the generators indirectly connected to the load through dielectric material, in State A;

FIG. 12 is the same embodiment of FIG. 11 except in State B;

FIG. 13 is the same embodiment of FIG. 11 except in State C;

FIG. 14 is the same embodiment of FIG. 11 except in State D;

FIG. 15 is a schematic diagram of an embodiment of the invention having continuous mechanical input providing a continuous wave (cw) electrical output with the generators directly connected to the load;

FIG. 16 is a schematic diagram of an energy conversion system of the invention wherein the system functions as a motor receiving electrical energy and delivering mechanical energy;

FIG. 17 is a pictorial-block-schematic diagram of an embodiment of the invention for receiving rotational energy from a mechanical source and delivering electrical energy to a load;

FIG. 18 is a schematic drawing shown a control system for maintaining a given maximum and minimum charge on the generating capacitors; and

FIG. 19 is a block-schematic diagram showing the improvement of the disclosed invention over a typical prior art system.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In embodiments of the invention, energy conversion is obtained for the Variable Capacitance Electrostatic Energy Conversion System by operation of variable capacitance electrostatic generators, involving contained charge, in paired opposition to one another across the load (or electrical source of power), either directly or indirectly through dielectric material, to provide for conversion of mechanical energy to electrical energy (or electrical energy to mechanical energy).

For a variable capacitance electrostatic generator, the electrical power input to the capacitor, P_e (watts), is equal to the increase in capacitor electrostatic field energy, W_{ef} (joules), per unit time, t (seconds), and the mechanical power output, P_M (watts):

$$P_e = (dW_{ef}/dt) + P_M$$

with

$P_e = Vdq/dt$

V = capacitor potential (volts)

q = charge on capacitor (coulombs)

and $W_{ef} = \frac{1}{2} CV^2$

C = capacitor capacitance (farads)

Also, $q = CV$

Therefore, $P_M = \frac{1}{2} V^2 (dC/dt)$

and the time rate of conversion of mechanical to electrical energy, dW_{ME}/dt, equal to $-P_M$, is given as

$$dW_{ME}/dt = -\frac{1}{2} V^2 (dC/dt)$$

Conversion of mechanical shaftpower to electrical power to a load by variable capacitance electrostatic generators operating in paired opposition to one another across the load (and involving contained charge) shall be considered first.

Examples of two specific physical arrangements of electrostatic generators operating in paired opposition to one another connected directly to a load R (ohms) are shown in FIGS. 1 and 2. Capacitance change is by rotary motion in the embodiment of FIG. 1 and reciprocating motion for the embodiment represented by FIG. 2. FIG. 2 is shown in partial schematic form in FIG. 3 and the electrical schematic diagram for the device of FIG. 1 is shown in FIG. 4. Referring to FIGS. 1 and 4, the capacitors 11 and 12 each range in value from high capacitance C_H to low capacitance C_L and are coupled by the drive shaft 13 so that they operate in opposition to each other; that is, when one capacitor has value C_H, the other capacitor has value C_L, and vice versa. The capacitors each are initially charged to possess a charge Q, and hence there exists a contained (or "trapped") charge of 2Q for the system. As variable capacitor **11** varies from C_H to C_L, its charge varies from $(Q + q_o)$ to $(Q - q_o)$; as variable capacitor **12** varies from C_L to C_H, its charge varies from $(Q - q_o)$ to $(Q + q_o)$. A charge $2q_o$ is directly transferred across the load **14**. As capacitor **11** is decreasing in capacitance mechanical energy is converted by it to electrical energy and electrical energy is converted to mechanical energy by variable capacitor **12** which is increasing in capacitance. However, since capacitor **12** is drive-shaft coupled to capacitor **11**, this mechanical energy may be considered as simultaneously reconverted to electrical energy. With rotation, capacitor **11** reaches the state initially occupied by capacitor **12** and capacitor **12** is now in the state initially occupied by capacitor **11**. As the drive shaft continues to rotate, the capacitors return to their respective initial states with another transfer of charge $2q_o$ across the load, and a cycle is completed.

A schematic-pictorial physical arrangement of the electrostatic generators operating in paired opposition to one another, indirectly connected to the load through dielectric (insulating) material, is shown in FIG. **5**; an electrical schematic diagram for this embodiment is shown in FIG. **6**. The advantages of using a dielectric as electrode material is well known as exemplified by U.S. Pat. No. 3,745,481 to patentees G. F. Erickson et al. In this embodiment for each cycle a charge of $4q_o$ is transferred by displacement across the load; there is charge q_o associated with the dielectric material capacitors of capacitance c_d.

The simplified embodiments presented above were for initial explicit exposition of the concept involved for the Energy Conversion System. The following embodiments, presented in more detail, will explain the operation of the system and aid in the comprehension of the invention.

The pulsed energy input systems with the generators directly connected to the load are perhaps the easiest to comprehend. The electrical schematic diagram of these embodiments is shown in FIG. **7**. It is similar to the electrical schematic diagram of previous FIG. **4** except for the added switch **20**. The pictorial diagram of FIG. **1** is also a suitable physical representation if a switch is placed in the line going to the load. The operation will be explained considering four states or positions of the capacitors after a movement from their prior state. It is assumed that the capacitors have been initially charged and that operation through previous cycles has taken place. The switch is triggered cyclicly as a function of drive shaft position.

State A (FIG. **7**): Capacitor **21** has capacitance C_H and a charge $(Q + q_o)$; capacitor **22** has capacitance C_L and a charge $(Q - q_o)$; the potentials (volts) across the capacitors are equal. (NOTE: The magnitude of the potentials associated with the various circuit elements are indicated by the relative length of the arrows in the schematics as presented in the figures, e.g., arrows **23** and **24**, with the tip of the arrow indicating the direction of increasing potential for the charge; the arrows, representing the potential, are not necessarily drawn to scale.) The switch is in closed position; the switch, for the purpose of this exposition, shall be considered as an ideal switch (that is, it has negligible inductance, infinitely small capacitance relative to other circuit elements, infinite resistance when open, and zero resistance when closed). The potential across a capacitor is equal to the charge on the capacitor divided by its capacitance, therefore;

$$(Q + q_o)/C_H = (Q - q_o)/C_L$$

The energy associated with the electrostatic field of a capacitor is given by one-half the value of its charge squared, divided by its capacitance. Therefore, the total electrical energy of the electric circuit in State A, W_A, is given as

$$W_A = \tfrac{1}{2}(Q + q_o)^2/C_H + \tfrac{1}{2}(Q - q_o)^2/C_L$$

The switch is opened and, as the drive shaft rotates, the capacitances of capacitors **1** and **2** change to State B.

State B (FIG. **8**): Capacitor **21** now has capacitance C_L and capacitor **22** has capacitance C_H. The total electrical energy for the electric circuit in State B, W_B, is given as

$$W_B = \tfrac{1}{2}(Q + q_o)^2/C_L + \tfrac{1}{2}(Q - q_o)^2/C_H$$

The potential rise across capacitor **21** is equal to the potential drop across the switch **20** and across capacitor **22**.

State C (FIG. **9**): The switch **20** is now closed. The potential rise across capacitor **21** is now equal to the potential drop across the load and the potential drop across capacitor **22**. It is assumed, for the purpose of this exposition, that the transient response time of the electric circuit is much faster than the time required for one complete cycle of the variable capacitors (that is, the time required for the variable capacitors, starting at respective initial states, to return to those respective states, as the drive shaft rotates). With q now representing the charge being transferred, the equation for the electrical circuit response is given as

$$(Q + q_o - q)/C_L = R\,(dq/dt) + (Q - q_o + q)/C_H$$

When $t = 0$, $q = 0$; when $t = \infty$, $q = 2q_o$.
The solution of the previous equation is as follows:

$$q = 2q_o[1 - \exp[-(1/R)\,(1/C_L + 1/C_H)t]]$$

And from the earlier equation $(Q + q_o)/C_H = (Q - q_o)/C_L$

$$q_o = \frac{(1/C_L - 1/C_H)}{(1/C_L + 1/C_H)}\,Q$$

State D (FIG. **10**): After charge rearrangement by a flow of current through the load, capacitor **22** is in the same state as capacitor **21** in State A; capacitor **21** is in the same state as capacitor **22** in State A; and the total electrical energy for the electrical circuit in State D, W_D, is given as

$$W_D = \tfrac{1}{2}(Q + q_o)^2/C_H + \tfrac{1}{2}(Q - q_o)^2/C_L$$

By subtracting this equation from the one in State B, it is seen that:

$$W_B - W_D = 2q_o^2\,(1/C_L + 1/C_H) = 4[\tfrac{1}{2}\,q_o^2(1/C_L + 1/C_H)]$$

-continued

$$ {}_{o}^{\infty} R\left(\frac{dq}{dt}\right)^2 dt = 2q_o^2(1/C_L + 1/C_H) = W_B - W_D $$

Electrostatic energy is delivered to the load. As the drive shaft **25** rotates, capacitors **21** and **22** will again go through States B and C, with their roles interchanged, until the capacitors return to their respective states as given in State A. For this second half of the cycle, the same amount of energy is delivered to the load as was delivered in the first half of the cycle; hence, the energy delivered to the load per cycle, W, is given as follows:

$$ W = 2(W_B - W_D) = 8[\tfrac{1}{2}\, q_o^2(1/C_L + 1/C_H)] $$

The limit on energy transfer may be determined as follows. The breakdown potential for the variable capacitors, V_{CB} (volts), may be related to the charge on the variable capacitors:

$$ (Q + q_o)/C_L = V_{CB} $$

By use of this equation and the one given at the end of State C, the limiting value of q_o may be given as follows:

$$ q_o = (C_L/2)\,(1 - C_L/C_H)V_{CB} $$

By substitution of the above value of q_o into the foregoing equation for W, the limit on W, W_{CB}, is given as

$$ W_{CB} = (1 + C_L/C_H)\,(1 - C_L/C_H)^2 C_L V_{CB}^2 $$

The range of W is then given as follows: $0 \leqq W < W_{CB}$

For non-negligible circuit inductance, such as, for example, a series inductance L (henries), the equation for the electrical circuit response is given as

$$ (Q + q_o - q)/C_L = R(dq/dt) + L(d^2q/dt^2) + (Q - q_o + q)/C_H $$

When $t = 0$, $q = 0$; when $t = \infty$, $q = 2q_o$; the solutions are given as follows.

For over damped response, $(R/2L)^2 > (1/L)\,(1/C_L + 1/C_H)$,

$$ q = 2Q[\frac{C_H - C_L}{C_H + C_L}]\,[1 - \exp\left(-\frac{Rt}{2L}\right)[\frac{R}{2La}\sinh(at) + \cosh(at)]] $$

With

$$ a = \sqrt{\left(\frac{R}{2L}\right)^2 - \frac{1}{L}\left(\frac{1}{C_L} + \frac{1}{C_H}\right)} $$

For critically damped response, $(R/2L)^2 = (1/L)\,(1/C_L + 1/C_H)$,

$$ q = 2Q[\frac{C_H - C_L}{C_H + C_L}]\,[1 - \exp\left(-\frac{Rt}{2L}\right) - \frac{Rt}{2L}\exp\left(-\frac{Rt}{2L}\right)] $$

For under damped response, $(R/2L)^2 < (1/L)\,(1/C_L + 1/C_H)$,

$$ q = 2Q[\frac{C_H - C_L}{C_H + C_L}]\,[1 - \exp\left(-\frac{Rt}{2L}\right)[\frac{R}{2Lb}\sin(bt) + \cos(bt)]] $$

With b being given by a, as defined above, divided by the square root of minus one. The relation between Q and q_o is

$$ q_o = \frac{(1/C_L - 1/C_H)}{(1/C_L + 1/C_H)}\,Q, $$

as previously stated.

An embodiment of the invention for operation with pulsed energy input and the electrical load connected through dielectric material, such as barium titanate, is schematically illustrated in FIG. **11**. This type of system is ideally suited for the production of molecular excitation and volume ionization of high-pressure lasing media. As in the previous embodiment, four states or end positions of arcs of rotational movement will be illustrated.

State A (FIG. **11**): Capacitor **31** has capacitance C_H and a charge $(Q + q_o)$; capacitor **32** has capacitance C_L and a charge $(Q - q_o)$. The potential rise across capacitor **32** is equal to the sum of the potential drops across each dielectric electrode (**33** and **34**, each of capacitance c_d) and capacitor **31**:

$$ (Q - q_o)/C_L = 2q_o/c_d + (Q + q_o)/C_H $$

The total electrical energy of the electric circuit in State A is given as follows:

$$ W_A = \tfrac{1}{2}\,(Q + q_o)^2/C_H + q_o^2/c_d + \tfrac{1}{2}\,(Q - q_o)^2/C_L $$

Switch **36** is opened and, as drive shaft **35** rotates, the capacitance of capacitors **31** and **32** changes, and state B is reached.

State B (FIG. **12**): Capacitor **31** now has capacitance C_L and capacitor **32** has capacitance C_H. The total electrical energy for the electric circuit in State B is given as follows:

$$ W_B = \tfrac{1}{2}\,(Q + q_o)^2/C_L + q_o^2/c_d + \tfrac{1}{2}\,(Q - q_o)^2/C_H $$

The potential rise across capacitor **31** and the two capacitances c_d equals the potential drop across the switch and capacitor **32**.

State C (FIG. **13**): Switch **36** is now closed. The potential rise across capacitor **31** and the two capacitances c_d equals the potential drop across the load and capacitor **32**. The equation for the electrical circuit response is given as follows:

$$ (Q + q_o - q)/C_L + 2(q_o - q)/c_d = R(dq/dt) + (Q - q_o + q)/C_H $$

When $t = 0$, $q = 0$; when $t = \infty$, $q = 2q_o$.

Solution of the equation is as follows:

$$ q = 2q_o[1 - \exp[-(1/R)\,(1/C_L + 2/c_d + 1/C_H)t]] $$

With, as given previously,

$$ q_o = \frac{(1/C_L - 1/C_H)Q}{(1/C_L + 2/c_d + 1/C_H)} $$

State D (FIG. **14**): After charge rearrangement, capacitor **32** is in the same state as capacitor **31** in State A; capacitor **31** is in the same state as capacitor **32** in State A; and the polarity of the charge on the dielectric capacitances has been reversed. The total electrical energy for the electric circuit in State D is given as follows:

$$W_D = \tfrac{1}{2}(Q + q_o)^2/C_H + q_o^2/c_d + \tfrac{1}{2}(Q - q_o)^2/C_L$$

By combining equations, it is seen that:

$$W_B - W_D = 2q_o^2(1/C_L + 2/c_d + 1/C_H) = 4[\tfrac{1}{2} q_o^2 (1/C_L + 2/c_d + 1/C_H)]$$

And that:

$$\int_0^\infty R\left(\frac{dq}{dt}\right)^2 dt = 2q_o^2(1/C_L + 2/c_d + 1/C_H) = W_B - W_D$$

Electrostatic energy is delivered to the load. As drive shaft **35** rotates, capacitors **31** and **32** will again go through States B and C, with their roles interchanged, until the capacitors return to their respective states as given in State A. For this second half of the cycle, the same amount of energy is delivered to the load as was delivered in the first half of the cycle; hence, the energy delivered to the load per cycle, W, is given as follows:

$$W = 2(W_B - W_D) = 8[\tfrac{1}{2} q_o^2](1/C_L + 2/c_d + 1/C_H)$$

Assuming q_o limited by the breakdown potential of the dielectric material, V_{dB}, $q_o = c_d V_{dB}$. Then, the limit on W, W_{dB}, is as follows:

$$W_{dB} = 4(c_d/C_L + 2 + c_d/C_H)c_d V_{dB}^2$$

The range of W is then given as follows: $0 \leqq W < W_{dB}$

FIG. **15** schematically illustrates an embodiment of the invention having continuous mechanical energy input and providing a continuous wave output to the loads. It is similar to previous FIG. **4** except for designations of charge and capacitance.

Consider the system schematic as shown in FIG. **15**; and, at time $t = 0$, the variable capacitors **41** and **42** have the same capacitance, the same charge Q, and hence are at the same potential. Capacitor **42** is out of phase with capacitor **41** by half a period; the capacitors vary periodically with period T (seconds).

The circuit equation for the transported charge q is as follows: assuming negligible circuit inductance:

$$(Q - q)/C_1 = R(dq/dt) + (Q + q)/C_2$$

with $q = 0$, for $t = 0$.

With sinusoidal input to the load, for the following assumed capacitance:

$$C_1 = \frac{1}{\frac{1}{C_H} + \left(\frac{1}{C_L} - \frac{1}{C_H}\right)\left[\frac{1 - \cos\frac{2\pi}{T}\left(t + \frac{T}{4}\right)}{2}\right]}$$

$$C_2 = \frac{1}{\frac{1}{C_H} + \left(\frac{1}{C_L} - \frac{1}{C_H}\right)\left[\frac{1 + \cos\frac{2\pi}{T}\left(t + \frac{T}{4}\right)}{2}\right]}$$

$$q = \frac{\frac{Q}{R}\left[\frac{1}{C_L} - \frac{1}{C_H}\right]}{\sqrt{\left(\frac{2\pi}{T}\right)^2 + \left[\frac{1}{R}\left(\frac{1}{C_L} + \frac{1}{C_H}\right)\right]^2}} X$$

$$\left[\begin{array}{l} \cos\left[\frac{\pi}{2} - \arctan\left(\left[\frac{2\pi}{T}\right] / \left[\frac{1}{R}\left(\frac{1}{C_L} + \frac{1}{C_H}\right)\right]\right)\right] \exp\left[-\frac{1}{R}\left(\frac{1}{C_L} + \frac{1}{C_H}\right)t\right] \\ -\cos\left[\frac{2\pi}{T}\left(t + \frac{T}{4}\right) - \arctan\left(\left[\frac{2\pi}{T}\right] / \left[\frac{1}{R}\left(\frac{1}{C_L} + \frac{1}{C_H}\right)\right]\right)\right] \end{array}\right]$$

with average power, P (watts), given, for the electrical circuit time constant,

$$1/\left[\frac{1}{R}\left(\frac{1}{C_L} + \frac{1}{C_H}\right)\right],$$

much less than T, and after transient decay, as follows:

$$P = \frac{1}{T}\int_t^{t+T} R\left(\frac{dq}{dt}\right)^2 dt = \frac{2\pi^2 R Q^2 (C_H - C_L)^2}{T^2 (C_H + C_L)^2}$$

and with Q limited by the breakdown potential V_{CB} of the capacitors as follows:

$$\left[\frac{(Q - q)}{C_1}\right]_{maximum} = \frac{Q(C_H + C_L)}{2C_H C_L} = V_{CB}$$

By use of these last two equations, the limit on P, P_{CB}, is:

$$P_{CB} = \frac{8\pi^2 C_H C_L (C_H - C_L)^2 V_{CB}^2}{T^2 (C_H + C_L)^3 \left(\frac{1}{R}\right)\left(\frac{1}{C_L} + \frac{1}{C_H}\right)}$$

The range of P is then given as follows: $0 \leqq P < P_{CB}$

As with the pulsed embodiments the load on the *cw* embodiments may be an electrostatic field between dielectric electrodes. It is also to be understood that the electrical outputs of generating embodiments of the invention, while generally of quite high electrical potential, may be rectified (and filtered), or run through a transformer effecting an impedance change, or any of the other conventional electrical changes and usages that are common practice with continuous wave or pulsed alternating current voltages.

It is also to be understood that for simplicity, only one movable and one fixed plate has been shown for a variable capacitor, and that embodiments may be constructed that have capacitors with many fixed and movable plates. A plurality of embodiments may be connected in series for providing higher output voltages and better voltage breakdown characteristics. The polarity of the charge placed on the capacitors, i.e., the common polarity of all the fixed plates of an embodiment with respect to the movable plates is immaterial.

The electrostatic energy conversion system of the invention may also be operated as a motor. FIG. **16** is a simplified schematic representation of an embodiment of the invention for receiving electrical energy from a power source **45** and providing torque to rotate shaft **48**. Variable capacitors **46** and **47** are similar to those in the generating device, with the capacitance of capacitor **46** being a maximum when the capacitance of capacitor **47** is a minimum. Shaft **48** is driven by the forces of the capacitor plates to rotate in synchronism with the frequency of source **45**. Thus, unless the frequency of source **45** is relatively slowly increased from dc to the desired operating frequency, other conventional means such as are normally used to get synchronous motors up to synchronous speed may be used to bring shaft **48** up to substantially synchronous speed with the line frequency of the source of electrical power before connection is made.

It is to be understood that the devices of the invention, generally like other electrostatic devices from a practical consideration, generally function with relatively high voltages compared to conventional electromagnetic equipment. As pointed out by Trump in the previously referenced AIEE (now IEEE) paper, two metallic plates of 100 square inches area which are parallel and insulated from each other, with an electric field of 300 volts per centimeter between them have an electrostatic force of attraction of about 0.0005 pound. If the active gradient is increased to 30,000 volts per centimeter, which is the highest voltage that can be insulated in atmospheric air, the electrostatic force between the plates is increased to little more than 0.5 pound. When the plates are immersed in a high vacuum and the gradient increased to 3 million volts per centimeter, the electrostatic force then becomes approximately 5,700 pounds.

From the foregoing, it is readily apparent that for embodiments of the invention to be practical, the variable capacitors should be operated in a high vacuum. For embodiments used in outer space, this is generally not a problem, but for terrestial embodiments, it is generally preferred that a sealed chamber having a high vacuum be used. Insulative gases such as sulphur hexafluoride or air at high pressures may be used instead of the high vacuum to provide the necessary insulation at the high voltages required for practical operation. Another reason for generally preferring the high vacuum environment for embodiments of the invention is the elimination of drag on the moving members. A complete system for the cw generation of electrical power under normal terrestial conditions is shown schematically in FIG. **17**. Variable capacitors **50** and **51**, with rotation, pass a contained charge back and forth between them causing a current to flow through load **52** delivering power to it. Driver **53** may be any suitable device that can supply the torque necessary to rotate the movable plates of the capacitors such as an electric motor, a turbine, or even a hand crank. Generally, it is desirable to provide conventional speed sensor **54** with conventional feedback control **55**, actuating energy input controller **56**, so that the frequency of the generated electrical energy supplied to load **52** is relatively constant. An initial charge is placed on variable capacitors **50** and **51** by momentarily closing switch **57** causing conventional high potential source **58** to place an equal potential charge of the same polarity on each capacitor. It is generally desirable to position the movable plates of the capacitors such that they have equal capacity when initially charged so that the initial charge magnitudes will also be equal. The capacitors are operated in a high vacuum in conventional sealed chamber **59**. Conventional vacuum pump **60** provides the high vacuum in the chamber (approximately 10^{-8} Torr). Mechanical drive shaft **61** extends through the chamber walls in magnetically sealed rotary motion feedthroughs **62** and **63**. These conventional, commercially available, sealed bearings having ferrofluid seals provide substantially zero leakage (at speeds up to 10,000 rpm) to a high vacuum on one side of the bearing seal and atmospheric pressure on the other side of the bearing. Conventional capacitor plate material such as stainless steel is suitable and generally preferable. Conventional high voltage feedthroughs **64** and **65** provide for transfer of charge from the stator capacitor plates to the load.

As previously stated, once the charge is placed on the capacitors it is not diminished or dissipated in supplying power to the load. It is a contained or trapped charge, and is not run down by the load. If the insulation within the chamber were perfect, the charge would never have to be replenished. Since nothing is perfect the charge will, over a long period of time, decrease. It may be replenished by momentarily actuating switch **57** as in the initial charging of the capacitors or the charge may be automatically held within predetermined maximum and minimum values on the capacitor plates by an electrical circuit as shown schematically in FIG. **18**. For simplicity of explanation, maximum voltage monitoring is shown on one side of the capacitor pair and minimum voltage monitoring on the other. It is to be understood that both a maximum and a minimum monitoring may be on the same side, or simultaneously on both sides, if desired. Potential source **70** and diode **71** add charge when the voltage potential of capacitor **72** is below that of source **70** when capacitor **72** is at maximum capacitance. Potential source **73** in cooperation with diode **74** removes charge when the voltage of capacitor **75** (when going through its minimum capacitance) is greater than the potential of **73**. By having potential sources **70** and **73** adjustable and controllable by conventional voltage monitor **76**, the correct value of trapped charge for the system is maintained for desired voltage (or power) for load **77**. The regulating system shown in FIG. **18** may also be used to compensate for leakage losses.

FIG. **19** illustrates in block schematic form the advantages of the disclosed invention in supplying a high potential to a load such as a laser. In the conventional prior art systems, shaft power **90** turns conventional electrical generator **91** generating relatively low voltage, high current energy, to operate conventional high voltage power supply **92** which changes capacitor **93** through resistor **94**. Capacitor **93** discharges when switch **95** is closed to supply the load **96** with energy. In the present invention, shaft power **90*a*** directly actuates inversely ganged capacitors **93*a*** and **93*b*** providing an electrostatic energy charge equivalent to that placed on capacitor **93** by power supply **92**. Thus, the closing of switch **95*a*** provides the same energy to the identical load **96*a*** as in the prior art system. In the illustration bipolar pulses flow to load **96*a***. If unipolar pulses are desired for the load **96*a*** as for load **96** in the prior art circuit, conventional rectification of the bipolar pulse may be used.

I claim:

1. An alternating current electrostatic energy converter comprising:

a. a first and a second variable capacitor, each having a maximum and a minimum capacitance, connected in paired opposition and inversely ganged such that one capacitor passes through a maximum capacitance as the other capacitor is going through a minimum capacitance;

b. means for placing an initial and contained electrical charge on the said first and second capacitors;

c. means for actuating the said capacitors through their maximum and minimum capacitance passing contained charge between them; and

d. means for extracting power from the said capacitors.

2. An electrostatic alternating current generating system comprising:

a. a first and a second variable capacitor, each having a maximum and a minimum capacitance, inversely ganged on a common shaft such that one capacitor passes through a maximum capacitance as the other capacitor is going through a minimum capacitance;

b. means for placing an initial and contained electrical charge on the said first and second capacitors;

c. means for actuating the said shaft moving capacitors through their maximum and minimum capacitance;

d. an electrical load; and

e. means for connecting the said first and second variable capacitors in paired opposition to one another across the said load whereby contained charge is passed back and forth between the said capacitors through the said load.

3. An electrostatic alternating current generator comprising:

a. a first variable capacitor having a fixed plate and a movable plate providing a maximum and a minimum capacitance between the said fixed plate and the said movable plate;

b. a second variable capacitor having a fixed plate and a movable plate providing a maximum and a minimum capacitance between the said fixed plate and the said movable plate;

c. means for mechanically coupling the said movable plate of the said first capacitor to the movable plate of the said second capacitor such that the capacity of one variable capacitor is at a maximum capacitance when the other variable capacitor is at a minimum;

d. means for electrically connecting the said movable plates;

e. means for placing a contained electrical charge on the said variable capacitors such that the said fixed plates have like polarity charge;

f. means for actuating the said variable capacitors through a change of capacitance; and

g. means for connecting an electrical load between the said fixed plates of the variable capacitors, whereby with change of capacitance of the said capacitors, contained charge is passed between the said capacitors through the said load.

4. The apparatus as claimed in claim 3 wherein the said means for placing a charge on the said variable capacitors includes means for placing equal initial charges on the said variable capacitors.

5. The apparatus as claimed in claim 4 wherein a means for providing an evacuated enclosure and a means for positioning the said first and second variable capacitors within the said evacuated enclosure are provided.

6. The apparatus as claimed in claim 5 wherein the said means for actuating the said variable capacitors is rotational.

7. The apparatus as claimed in claim 5 wherein the said means for actuating the said variable capacitors is reciprocating.

8. A synchronous alternating current electrostatic motor comprising:

a. a first and a second variable capacitor each having a maximum and a minimum capacitance, connected in paired opposition inversely ganged on a common shaft such that one capacitor passes through a maximum capacitance as the other capacitor is going through a minimum capacitance;

b. means for placing an initial, contained, electrical charge on the said first and second capacitors;

c. means for placing an alternating potential voltage on the said first and second capacitors; and

d. means for connecting a mechanical load to the said shaft.

SELF-STARTING ELECTROSTATIC GENERATOR

Norman H. Lehrer, Bloomfield, N. J., assignor to Chatham Electronics Corporation, Newark, N. J.

Application September 25, 1952, Serial No. 311,360

5 Claims. (Cl. 310—6)

The subject matter of this patent may be used by or for the Government for governmental purposes without the payment of any royalties to me.

This invention relates to influence type electrostatic generators, specifically those employing feedback, and has particular reference to an arrangement of components which provides reliable starting action and which always starts with the same polarity.

Prior art generators of the induction type are not self-starting and a separate source is generally used to apply a charge to one of the induction plates to start the generator. The separate source can be a friction generator, a battery, or any other source of direct current power.

The present machine is an improvement over prior art machines in that it provides reliable starting action with the desired polarity without requiring additional parts. Reversal of polarity caused by polarization of a dielectric covering the stator plates is prevented by leaving the stator plates uncovered.

One of the objects of the present invention is to provide an improved electrostatic generator which avoids one or more of the disadvantages and limitations of prior art generators.

Another object of the invention is to provide an electrostatic influence generator which always starts its generating action without separate excitation.

Another object of the invention is to provide an electrostatic generator which always starts with the same polarity.

Another object of the invention is to reduce the cost and complexity of self-starting generators by using only the parts generally employed in generators that are not self-starting.

The invention comprises an electrostatic generator which includes a disk shaped rotor containing a number of conducting sectors imbedded in the rotor insulating material. Brush contact with the conducting sectors is made at the edge of the rotor disk where small portions of the sectors project. One of the collecting brushes is made of molybdenum or similar material and, in addition to making contact with the sector portions, rubs against the edge of the insulator disk, causing a charge to be generated due to frictional phenomena. The usual set of stator influence plates is mounted close to the disk surface for inducing a charge in the rotating sectors. One of the stator plates is separated from the disk surface a greater distance than the other plates. One set of brushes is connected to a diametral conductor which isolates charges on the sectors as they pass through the field of the stator plates. Another set of brushes, connected to the stator plates, keeps the plates charged and produces the voltage for the load circuit.

For a better understanding of the present invention, together with other and further objects thereof, reference is made to the following description taken in connection with the accompanying drawings.

Fig. 1 is a plan view of an electrostatic influence generator shown partly in schematic representation.

Fig. 2 is a side view of the generator showing the arrangement of the brushes.

Fig. 3 is a cross sectional view of the rotor taken along line 3—3 of Fig. 2.

Referring now to the figures, a rotor **10** is made of non-conducting material such as Lucite and is mounted for rotation on a central shaft **11**. This shaft may be turned by any convenient means, by hand, or by an electric motor. Imbedded in the body of rotor **10** are a number of conducting sectors **12**, formed in a wedge-shaped outline with a small tab portion **13** which extends to the periphery of the disk to make contact with a brush or collector electrode.

The conducting sectors **12** may be positioned in the rotor body as indicated in Fig. 3, in a single plane, or they may be mounted in a dual plane arrangement in overlapping positions in order to increase the current output.

In order to induce an electric charge on the sectors, four induction stator plates **14**, **15**, **16**, and **17** are mounted in the positions shown, close to the rotor face. These plates are insulated from the rotor only by an air gap. Plate **14** is mounted a greater distance from the rotor face than the other plates. The stator plates are secured by conductive brackets **18** and **19** which also serve as supports for two of the brushes which make contact with the rotor edge.

Four brushes **20**, **21**, **22**, and **23** are mounted around the periphery of the disk to make contact with the sector tabs as they revolve. Two of these brushes **20** and **21** are connected by the well known diametral conductor which is generally a component of all electrostatic induction generators and which segregates the charges on the sectors as they pass through the electric field of the stator plates.

Brushes **22** and **23** are connected to stator plates **14**, **15** and **16**, **17** respectively. They collect part of the charge of the rotating sectors to maintain the stator plates at maximum potential.

One of the diametral brushes **20** is made of molybdenum and is mounted a little out of line so that part of the brush rubs on the edge of the rotor insulation. This rubbing action generates sufficient frictional charge to start the machine. Any one of the brushes **20**, **21**, **22**, and **23** can be positioned so as to function as a brush and also to generate the frictional electric charge needed to start the machine. Also a separate brush can be added to generate this charge if desired.

Two terminals **25** and **26** are provided for connecting to a load circuit. These terminals are connected to the stator plate combinations **14**, **15** and **16**, **17**. An insulating base **27** acts as a support for all the components including the rotor shaft **11**. Either terminal may be grounded.

The operation of the generator is as follows: at the start let it be assumed that all parts of the machine are at zero potential and no accumulated charge exists on any of the plates or sectors. Power is applied to the rotor and as it revolves the rubbing of brush **20** along the surface of the rotor insulator generates an electrical charge, some of which resides at the upper edge of the rotor. This charge, which is positive in the case of molybdenum against Lucite, induces negative charges on both stator plates **14** and **16**. Since plate **16** is closer to the charged surface on which the positive charge resides it has a negative charge of higher voltage induced on its lower surface than the negative charge on the lower surface of plate **14**. When the rotating sectors are brought within the range of influence of these stator plates, the sectors under plate **16** are charged with a greater positive potential than the sectors under plate **14** and when the diametral conductor **24** makes and breaks the connection between the sectors, the sector under plate **14** is charged negatively and the sector under **16** is charged positively.

When the sectors move away from the stator plates, their potential increases as the capacity decreases in accordance with the well known law which states that the quantity of electricity is equal to the product of the capacity and the potential. When the sectors arrive at the opposite plate their charge is collected by one of the brushes **22** or **23** and the stator plates are charged to a higher potential. This cumulative process continues until leakage or a load limits the potential to a maximum value.

The potential of an isolated conductor in an electric field is proportional to the work done upon it to move it from one portion of the field to another. Moving the sectors from an oppositely charged plate such as **16** increases the potential in proportion to the decrease in capacity and in a similar manner, moving the sectors toward a similarly charged plate such as **14** also increases the potential in proportion to the increase in capacity.

The above is believed to be a correct explanation of the principles underlying applicant's invention. However, further investigation may lead to a modification of this theory. It is to be understood that the invention is independent of any theory that may be advanced to account for the results obtained.

While there have been described and illustrated specific embodiments of the invention, it will be obvious that various changes and modifications

may be made therein without departing from the field of the invention which should be limited only by the scope of the appended claims.

I claim:

1. A self-starting electrostatic influence generator comprising; a rotor made of insulating material; a plurality of conducting sectors imbedded in the rotor material, each having a connection to the surface of said rotor; a pair of conducting stator plates mounted adjacent to the rotor, one of said plates mounted at a greater distance from the rotor than the other; a diametral conductor connecting brushes on opposite sides of the rotor, said brushes mounted to make contact with said sector connections as the sectors pass through the electric field of the stator plates; a pair of collector brushes, each connected to a stator plate and mounted to make contact with said sector connections as the sectors pass into the electric field of the stator plates; and a brush mounted so as to rub on the rotor insulating material.

2. A self-starting electrostatic influence generator comprising; a rotor made of insulating material mounted for rotation on a shaft; a plurality of conducting sectors imbedded in the rotor material, each having a connection to the surface of said rotor; a pair of conducting stator plates mounted adjacent to the rotor, one of said plates mounted at a greater distance from the rotor than the other; a diametral conductor connecting brushes on the opposite sides of the rotor, said brushes mounted to make contact with said sector connections as the sectors pass through the electric field of the stator plates; a pair of collector brushes, each connected to a stator plate and mounted to make contact with said sector connections as the sectors pass into the electric field of the stator plates; one of said brushes mounted so as to rub on the rotor insulating material.

3. A self-starting electrostatic influence generator comprising; a rotor disk made of insulating material mounted for rotation on a shaft; a plurality of conducting sectors imbedded in the rotor material equally spaced and insulated from each other, each of said sectors having a connection to the surface of said rotor; a pair of conducting stator plates mounted adjacent to the rotor, one of said plates mounted at a greater distance from the rotor than the other; a diametral conductor connecting brushes on the opposite sides of the rotor disk, said brushes mounted to make contact with said sector connections as the sectors pass through the electric field of the stator plates; a pair of collector brushes, each connected to a stator plate and mounted to make contact with said sector connections as the sectors pass into the electric field of the stator plates; one of said brushes mounted so as to rub on the rotor insulating material and generate frictional charges thereon.

4. A self-starting electrostatic influence generator comprising; a rotor disk made of insulating material and mounted for rotation about an axis normal to the disk faces; a plurality of flat conducting sectors imbedded in the rotor material, insulated from each other and parallel to the disk faces; each of said sectors having a connection to the periphery of the rotor; a pair of conducting stator plates mounted parallel to the rotor faces, one of said plates mounted at a greater distance from the rotor face than the other; a diametral conductor, terminated by brushes on opposite sides of the rotor disk, said brushes mounted so as to make contact with the sector connections

as the sectors pass through the electric field of the stator plates; a pair of collector brushes, each connected to a stator plate and mounted so as to make contact with said sector connections as the sectors pass into the electric field of the stator plates; one of said brushes mounted so as to rub on the rotor insulating material and generate frictional charges thereon.

5. A self-starting electrostatic influence generator comprising; a rotor disk made of insulating material and mounted for rotation about an axis normal to the disk faces; a plurality of flat conducting sectors imbedded in the rotor material, insulated from each other and parallel to the disk faces; each of said sectors having a connection to the periphery of the rotor where contact can be made with one or more stationary brushes; a pair of conducting stator plates mounted adjacent to the rotor faces and parallel thereto, one of said plates mounted at a greater distance from the rotor face than the other; a diametral conductor, terminated by brushes on opposite sides of the rotor disk, said brushes mounted so as to make contact with the sector connections as the sectors pass through the electric field of the stator plates; a pair of collector brushes, each connected to a stator plate and mounted so as to make contact with said sector connections as the sectors pass into the electric field of the stator plates; one of said diametral or collector brushes mounted so as to rub on the rotor insulating material as well as to make contact with the sector connections.

Energy Harvesting Suits Remote Low-Power Devices

Wed, 02/02/2011 - 10:08am by Jon Titus, Senior Technical Editor

Grabbing "free" energy involves more engineering than buying an off-the-shelf transducer.

Jon Titus

Contrary to what you might think, the awareness of "green power" didn't spawn the drive to harvest energy. Low-power electronic fabrication technologies did the trick. They cut the power needs of small monitoring devices to the point where energy harvesting has started to make engineering and economic sense.

When engineers start to think about using energy-harvesting techniques to power a device, they must consider the power path. "You have an energy-harvesting device followed by an energy-conversion device, an energy-storage component, and ultra-low-power energy-management circuitry," said Steve Grady, vice president of marketing at Cymbet. "Although there is a lot of talk about 'battery-less' devices, energy-harvesting-based systems still need something to store energy for times when the energy transducer is inactive."

"A piezo-electric device can generate 10's to 100's of Volts while thermo-electric device or small solar panels generate microamps and millivolts," said Adrian Valenzuela, product marketing engineer at Texas Instruments. "So your power-management ICs must work with power across a wide range of currents and voltages. Say you need well-regulated 3-Volt power for an MCU," noted Valenzuela. "For some types of energy storage, you also need a low-power circuit to produce a well-regulated 4.2-Volt output to charge an energy-storage device."

"Energy-harvesting equipment needs an energy-storage device that has a high energy density, small size, and supports thousands of charge/discharge cycles" said Grady. "An energy-storage device also should exhibit a flat voltage profile and very low self discharge."

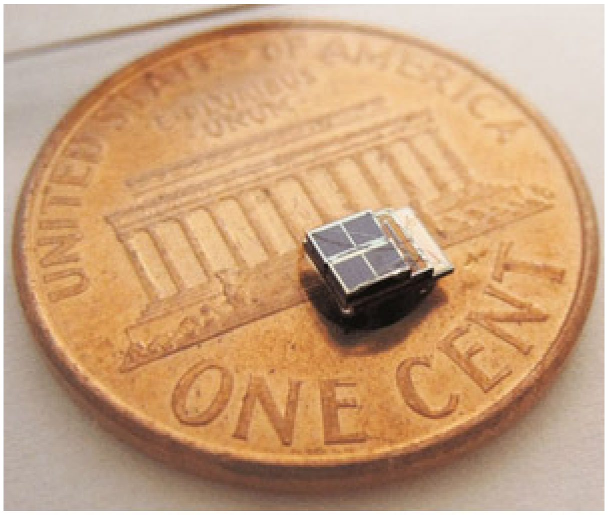

Figure 1. A Cymbet EnerChip placed on a penny shows the relative size of the energy-storage and -management circuits available now for energy-harvesting devices.

Figure 1. A Cymbet EnerChip placed on a penny shows the relative size of the energy-storage and -management circuits available now for energy-harvesting devices.

Cymbet manufactures rechargeable EnerChip solid-state batteries that offer energy storage in small SMT devices that can go through a reflow oven with other SMT ICs and components. The company's CBC3112, for example, provides a 3.3-V output at 12 uAh with an integrated power-management IC in a 7-by-7-mm SMT package. An EnerChip can go through more than 5000 charge/discharge cycles at a 10-percent depth of discharge.

In addition to figuring out how to gather, manage, and store energy, engineers face another challenge: money. "A battery costs 15 cents, so an energy-harvesting device cannot compete on cost," said TI's Valenzuela. "For now, engineers must work with exotic materials and devices, and they pass their high material costs on to consumers. In the majority of applications where engineers have a technical need for energy-harvested power the final decision almost always rests on the total cost of ownership."

"We also need to teach engineers how to think about power efficiency," noted Valenzuela. "Getting them to write energy-aware software is not easy, particularly when their application includes a wireless link. A wireless transceiver requires several orders of magnitude higher power than an MCU. So you must know how to compress data so it takes less time to transmit. And you must choose an antenna that produces the most efficient wireless signal for your equipment."

"We put a lot of effort into 'low-power firmware,' for a solar-energy-harvesting kit we created with Microchip," said Steve Grady of Cymbet. "When a harvester generates only a few microwatts or milliwatts, every Joule is precious. Inefficient use of a wireless transmitter at system start-up, for example, could completely drain the power source as a node searches for other wireless devices."

"We always have to coach our customers interested in energy harvesting about changing some of their code," continued Grady. "They just want to replace their existing power source with an energy-harvesting device, but that approach won't work. Sometimes success of a product depends as much on optimized firmware as on the harvesting device, energy storage and power-management circuitry."

Today the market for energy-harvesting devices seems a mile wide and an inch deep. "Every application is different," said Chris Ludlow, director of mechanical engineering, at Midé, a manufacturer of piezo-electric energy harvesters and electronics. "There's no silver-bullet product we can make to sell to 1000 customers. Vibration-type energy harvesters for devices on the the Golden Gate Bridge in San Francisco won't be the same as those for the Zakim Bridge in Boston because they have different vibration characteristics. We couldn't make a single product that would work on every bridge."

Don't feel discouraged by the challenges of harnessing "free" energy. Companies have created interesting and innovative harvesting technologies, power-management ICs, energy-

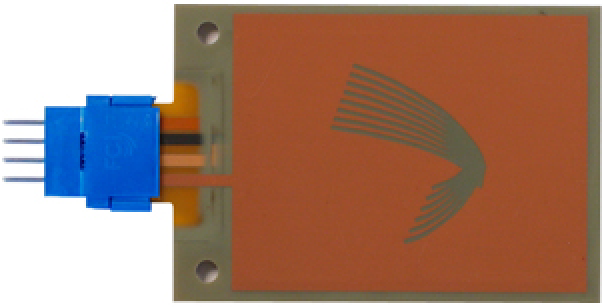

Figure 2. This image from Midé shows a "raw" Volture energy harvester engineers can use in a prototype or in an end product to convert vibrations into electrical energy. In this form, the harvester does not include any power-management circuits or energy-storage capability.

Titus-Figure 2

storage devices, as well as low-power MCUs and wireless transceivers.

Midé, for example, sells a line of standard harvesters that pick up vibrational energy with a piezo-electric transducer and convert it to electric power. "Piezos are brittle materials and they generally don't do well in harsh environments," said Ludlow. "But our packaging process protects the piezos and makes them easy to connect so you can put them into a product and have a reliable energy source."

"Many industries employ AC motors that create vibrations between about 50 Hz and 240 Hz, so you could use a standard piezo harvester on a motor to gather energy," noted Ludlow. "Then your device could report motor conditions to other equipment. Our main focus is on helicopters or rotary-wing aircraft where the vibration frequency range goes from about 10 Hz to 40 Hz. We also create under-train railway devices that operate in the 100-Hz range."

As Ludlow noted earlier, no one vibration harvester fills all needs. To help engineers understand vibration frequencies available on site, Midé created the SlamStick, a rechargeable USB-stick data logger that measures acceleration in all three axes. Configuration software lets users tailor the device to their specific needs. "Within 60 seconds we can characterize the vibration profile of a pump, for example, to find the best frequency for energy harvesting," said Ludlow. "That's the first type of analysis engineers should do for a vibration energy-harvesting application."

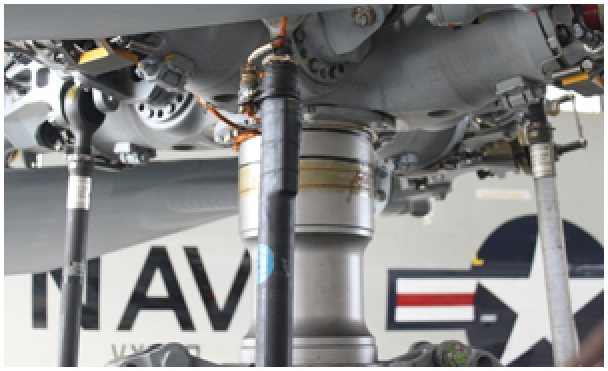

Figure 3. This photo shows a MicroStrain energy-harvesting pitch-link node installed on an Sikorsky MH-60S used for flight testing. The US Navy installed a connector on the pitch link to let people collect slip-ring data from a separate, hard-wired strain gauge as they also collected data from a MicroStrain wireless pitch-link load sensor.

Titus-Figure 3

MicroStrain also produces piezo-electric energy-harvesting devices for use in helicopters. "We're now involved with flight tests on MH-60S Navy Sea Hawk and UH-60A Army Black Hawk helicopters and V-22 Osprey tilt-rotor aircraft," said company President, Steve Arms. "Our harvesters convert the operational strains and vibrations of a helicopter into power that lets us monitor loads on rotating components. And we transmit the loads' information in real time."

"You might be surprised at the energy available in a device where you didn't think it existed, particularly at higher frequencies," noted Arms. In helicopter gearboxes, for example, we see a small displacement but because it shakes at such high frequencies, we can get a lot of energy. Even though the gearbox doesn't feel like it moves much, it is a rich environment for energy harvesting."

MicroStrain makes a product that can help engineers explore energy harvesting. The EH-Link Energy Harvesting Wireless Node lets people use piezo-electric, inductive, electromagnetic-field, solar, thermoelectric and other harvesting devices as power sources. The module includes an embedded triaxial accelerometer, relative-humidity and temperature sensor, and a single-channel differential input for an external sensor. Communications use a standard IEEE 802.15.4 transceiver.

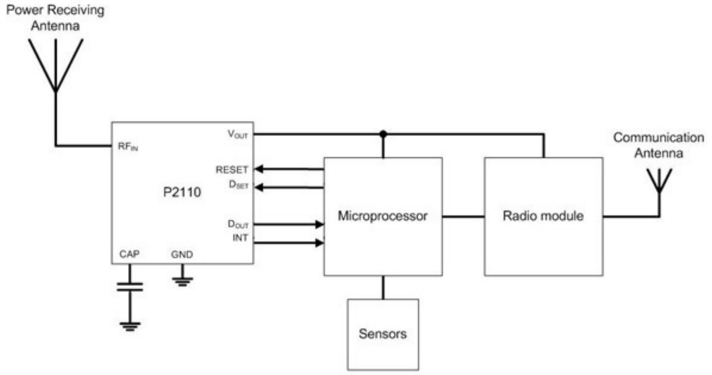

Figure 4. This block diagram shows the Powercast P2110 Powerharvester receiver IC provides RF energy harvesting and power management for battery-free, micro-power devices. A microprocessor can communicate with a P2110 and help improve system efficiency.

Titus-Figure 4

Not all energy you harvest comes from "free" vibrations, temperature differences, or sunlight. Sometimes you must pay a little extra to create the energy in the first place. Powercast takes that approach with its radio-frequency energy-harvesting devices, the P1110 and P2110 receivers that operate between 850 MHz and 950 MHz.

The wireless-harvesting technology provides controllable and reliable power that doesn't rely on intermittent sources. "You can turn on a Powercaster transmitter and provide power for as long as needed," said Harry Ostaffe, vice president of marketing and business development at Powercast. "Once charged, the receiver nodes can transmit their data or send a message to say 'Turn off the power, we’re fully charged.'" The TX91501 transmitter produces a 3-Watt output effective isotropic radiated power (EIRP) at 915 MHz and the companion receivers can pick up that energy from 40 to 50 feet (12 to 15 m) away.

"Along with power, the transmitter sends fixed data such as an identification code," noted Ostaffe. "And an MCU at the receiver could interpret that data for device authentication and location tracking. The data could also provide timestamps for remote devices that lack a real-time clock."

"Adopting the Microchip MiWi protocol let us use less power for each data transmission so the sensor node can operate more frequently while still maintaining its energy balance," said Ostaffe. "That's a benefit for a control application such as an HVAC system. And because RF power is available at all times and the receiver needs no battery, people can place sensors between walls and in toxic or dirty areas where there is no wind or light, or that would be inaccessible or dangerous for battery replacement."

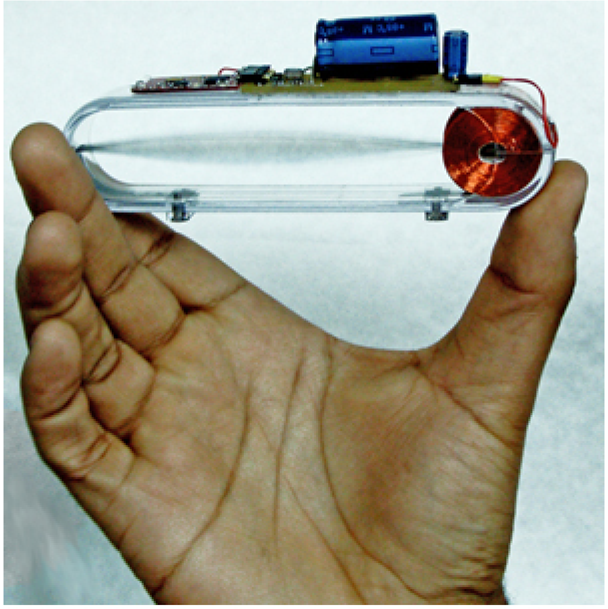

Figure 5. The tensioned membrane in this prototype from Humdinger Wind Energy moves a magnetic field through coils to create energy from wind at speeds of 6 meters/sec. or greater.

Titus-Figure 5

Some energy-harvesting devices show promise but haven't yet found a large market. Look, for example, at the approach taken by Humdinger Wind Energy. The company invented the Windbelt technology that harnesses wind energy in devices that can range from palm-size up to several meters across.

"We use a tensioned membrane that has magnets mounted on it," said Shawn Frayne, Humdinger's president and co-founder. "As air flows across the membrane it undergoes aeroelastic flutter. It's the same effect that ripped apart the Tacoma Narrows Bridge in 1940. When the membrane reaches a limit--a stable positive-feedback loop between competing lift and tension forces in the structure--we can extract power from a coil as the magnets change the field through it. With a wind speed of six meters per second (about 13 or 14 miles per hour), we can obtain from a milliwatt up to several milliwatts in a pack-of-gum sized system.

According to Frayne, Humdinger makes custom units for people who want to explore energy harvesting on different scales; however the technology is still very much "in the lab." But Frayne sees many potential uses wherever people have enough fluid flow they can tap for energy.

From the business direction, Frayne seeks to work with partners who can create complete products. "I don't see a situation where someone buys a wireless sensor node from Company A and then says, 'Let's power this with a windbelt.' They probably want to buy a little block that has all the wireless sensors and includes a windbelt."

"There's always interest in energy harvesting," said Frayne. "Everyone's just waiting for the market to blossom."

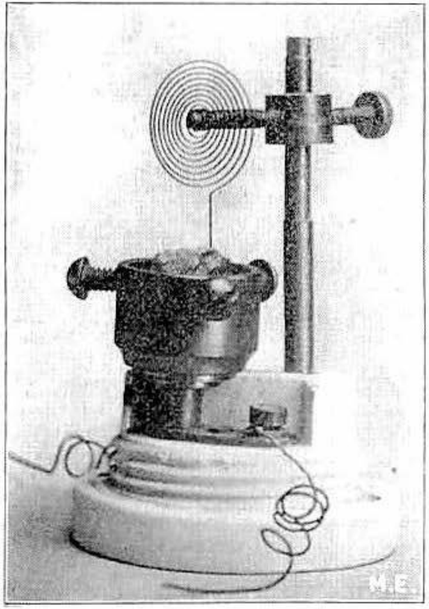
A GALENA DETECTOR

Herewith is a photo of my detector. It works well, and needs no descriptive matter to work by.

The whole surface of the Crystal "Galena" can be easily searched, by gently lifting the spring with a match and letting it down again.



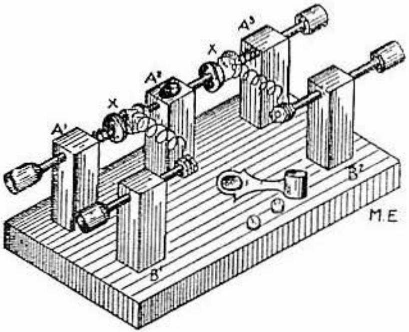
Modern Electrics has a good circulation in this colony, and is very popular.

Contributed by

W. F. HALL, Australia.

COMBINATION GALENA DETECTOR.

This detector is used in case a quick change is necessary. If one of the points of this detector happens to be knocked out of adjustment by static or other means the other detector can be easily thrown in the circuit by making use of the two point switch. The arm of this switch is connected to one side of the circuit while the points are connected to B1 and B2. The base of this detector, or A1, A2, A3, are all connected together and led to the other side of the circuit. You will find that this detector can be adjusted to the highest degree of sensitiveness, and is easy to construct, its dimensions being made according to your liking; but I would suggest, for the uprights, ½ inch square brass rod, each 1 inch high. The distance between A1 and A2 1¾ inches, and 1 inch between A1 and B1. The springs between X and A1 will hold the mineral in tight adjustment, while the check nut in A2 holds the other rod from slipping.



Contributed by

JESSE SAUTER.

CONTACT FOR LOOSE COUPLER

While building a loose coupler of the style described in "How to Make Wireless Instruments," the idea of placing two springs on my secondary to make contact with the rods did not seem very good to me, so I bought two brass curtain rods, 3/16 inches diameter, of the kind that has a small tube sliding into a slightly larger one. I used the small tubes for the rods on which the secondary slides, and after cutting two pieces of the larger tube the length of my secondary, I soldered one end of the wire wound on the secondary to one large tube and the wire from the switch to the other tube. I then placed the tubes in holes bored one inch above and below the center of the end pieces of the secondary. I find that it is possible to obtain a better contact by this means than by the springs, because the whole weight of the secondary lies upon the brass tubes, and I also find that the secondary slides much easier this way.

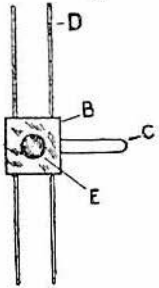
Contributed by

T. E. JONES.

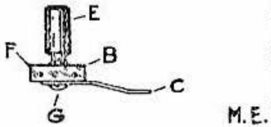
A TUNING COIL SLIDER.

The rod is made of two No. 14 brass wires, D.

The slider is made of a brass block, B, three-eighths inch square and one-eighth inch thick. Two holes are drilled one-sixteenth inch from the edge, F, so that the wires will just fit the holes.



The spring, C, is to make contact with the tuning coil wire, and is fastened to the block, B, by means of the battery binding post, G, and the hard rubber knob, E.



The brass wires are fastened to the tuning coil ends by means of brass screws.

Contributed by
BERTHEL CARLSON.

AN ADJUSTABLE CONDENSER.

The condenser consists of 10,000 square inches of tin foil and wax paper, made up in seven sections as per sketch; 14 pieces of brass, 1 inch by 1 inch by 3-16 inch, and 2 pieces ½ inch by 3-16 inch by 7¾ inches; 14 binding posts; and 12 plugs to fit holes as per sketch. The condenser is made up in the regular way, first a sheet of wax paper, then a sheet of tin foil, until seven condensers have been made. It will be seen by the sketch, which is very plain, that there is practically no limit to the different capacities that can be obtained. This condenser can be used for primary circuits or tuning, and is a very useful instrument around the laboratory for experimenting purposes. The tinfoil sheets can be cut any size to suit the maker. It is understood that this condenser cannot be used for secondary purposes.

HOW TO MAKE AN EXHAUSTED COHERER.

Procure 44 inches of glass tubing such as is used in a chemical laboratory, about one-quarter of an inch in diameter. Take a dime and cut from it two disks, B, about one-quarter of an inch in diameter. Next get two inches of copper or brass rod one-quarter of an inch in diameter and cut it into two pieces each one inch long. Solder the silver disks to one end of each of these rods, E, neatly. Next get two pieces of No. 22 platinum wire, each one and a half inches in length; drill a small hole in the other end of the rods and solder the wire in these as in E.

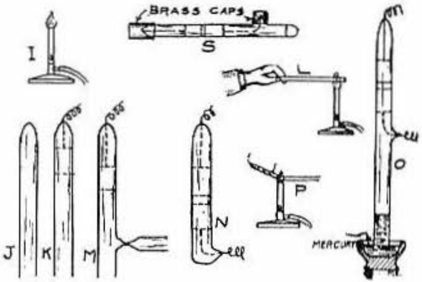
G- BRASS CAP
H.- TUBE WITH PLUG IN.

The next is a delicate job. Both of these plugs are filed to fit the tube



snugly and also must be airtight. Extreme care should be taken not to break the tube, as it must be over forty inches long. Next seal the plugs in the tube. You will need a small bowl, some mercury, and burner, also a helper. Hold one end of the tube over the flame until it is red-hot as in L. Then seize with the fingers and draw it out to a point; break this off about one-quarter of an inch from the long end and the end will look like J. Slip one plug through the open end and draw the platinum wire through the small end; hold this over the flame, and the glass will adhere to the platinum. Measure about four inches from the sealed end and hold it in the flame; also hold another piece of tubing in the flame at the same time; when both are hot touch the small piece to the long piece at the four-inch mark and draw out a small tip, as shown at M. Break off the short piece and leave the tip. Place the filings in the tube, made of 94 per cent. nickel and 6 per cent. silver. These can be obtained from coins, using a clean new file. Slip the other plug into position and pull the platinum wire through the tip, as shown at N. Space the plugs one-sixteenth of an inch apart, and seal off this tip as was the first. The tube is now filled with mercury, using a funnel, tap the tube so as to expel all the air bubbles. Fill this tube completely and place your thumb on the end. Invert, and place the open end under the surface of the mercury, then release your thumb. Then with the aid of a helper seal off the tube above the mercury level, as the mercury will drop to the thirty-inch level as in P. Place brass caps over the sealed ends, making contact with the platinum wire. The instrument is now ready for use.

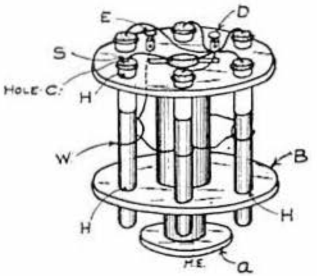
FANNON BEAUCHAMP.

LEYDEN JAR CONDENSER.

The materials needed for the construction of this condenser are: two wire spools, one about six inches in diameter, the other three inches, the larger being four inches high, the smaller three inches in height; six test tubes, with corks to fit; enough tinfoil to cover both outer and inner sides of the tubes; two binding posts, and four or five feet of green flexible wire.

To begin construction, smaller spool a is glued to bottom of larger spool b, to form a stand. Then six ¾-inch holes H are bored straight through both butts. Care must be taken to get these holes spaced evenly apart.

The test tubes, after being covered with the tinfoil by gluing, are slipped into the holes in the stand forming the Leyden jars. The corks have a hole c bored through their middle, in which is inserted a wire S, connecting the inner covering of tinfoil to binding post d. Then wires are wrapped tightly around the outside covering of the tubes w, connecting to binding post e.



After varnishing, the device is ready for work.

JOHN B. BRADY.

A PORTABLE RECEIVING OUTFIT.

Below is described a portable wireless outfit smaller than a small camera, in which sensitiveness is not sacrificed to saving of space.

It consists of a variometer, a condenser contained within the inner coil, and a detector of any type preferred by the maker.

The variometer consists of a cardboard cylinder, 1⅞x3½ inches in diameter, with the inner cylinder 3 inches outside diameter. Both cylinders are wound with an equal amount of No. 24 B. & S. gauge enameled wire. In placing the inner coil in position, a brass piece as shown in Fig. 1 may be found convenient to screw into the brass rod, if the outer coil is not sufficiently flexible to allow the rod to go through both holes.

A ROTARY TUNING COIL.

The following is a description of my double slide, rotary, and very accurate tuner. The circle and base are of 1 inch stock, the circle being wound with No. 24 enameled wire. The novel part is that each slider works independently, and that they are insulated from one another. It is connected into the circuit the same as any other double slide tuner. Drawing is self-explanatory.

TUNING TRANSFORMER.

As anybody knows who has tried it, the making of a transformer for tuning is a difficult job, and also a very clumsy one. Another objection is the expense of material. A very efficient substitute can be made as follows: Cut out a disk of wood one inch thick and about four inches in diameter. Then cut a groove on the circumference about half an inch wide, and a quarter inch deep, as per illustration. Then wind about a hundred turns of No. 36 insulated copper wire on this disk, leaving the ends for attaching to binding posts. Over this wind twenty turns of No. 22 copper wire in the same direction, having insulated it well from the No. 36 wire, also leaving leads for two binding posts. Then on positions indicated in diagram, screw

in binding posts, connecting the ends of the wires, one to each binding post, and mark them. Here we now have a condensed form of tuning transformer, with a very short wave length. A tuning coil is now connected in series with this instrument, and we have an arrangement which tunes sharper and with much less trouble than the ordinary tuning transformer, and costing a great deal less, as almost every amateur possesses a tuning coil. The No. 22 wire is connected in the aerial circuit, and the No. 36 in the receiver circuit. I have found this to work as good as a regular tuning transformer.

WALLACE ELLS.

ADJUSTABLE CONDENSER—FOR SENDING ONLY.

First, select six or eight thin table glasses, free from bubbles and cracks. It is best to wax the tops of each glass to prevent leakage. (See Fig. 1.)

Second, get a metal pan which will hold all of the glasses, and which is of the same height as the glasses.

The pan should be mounted on a base, provided with two binding posts. To one of the binding posts a wire is fastened, which, in turn, is soldered to the pan.

After the pan is fastened to the base, two uprights are provided, which are fastened to the base, about four inches from the pan. Between the uprights, a metal rod is suspended, from which wires are dropped down into each glass; and which is connected to the other binding post. (See Fig. 2.)

The glasses are now filled with a solution of salt and water.

The capacity of this condenser is varied according to the amount of solution in the pan; or if a large capacity is required, the pan is filled with this solution up to the top. If a low capacity is required, the solution in the pan may be but a few inches. Thus the capacity of the condenser is varied according to the amount of solution in the pan.

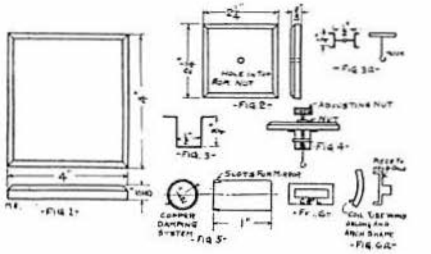
JAY JAKOWSKY.

HOW TO MAKE A SENSITIVE GALVANOMETER.

Finding the need of a good galvanometer, and one that would be very sensitive, without paying a high price for one, I succeeded in working out the following:

Make a base 4x4x⅝ inches thick, of mahogany or walnut and bevel the edges as shown in Fig. 1. Make two standards or sides, 2¼x3¼x½ inches. Fasten these to the base, with some good glue, 2¼ inches apart (inside measurements).

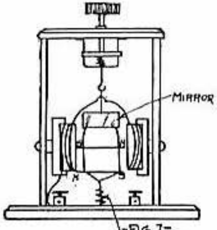


Now make a top of the same material as the base, size 2¾x2¼x⅝ inches, and bevel the top edges of this. Drill a hole in the center, large enough to admit a battery nut, see Fig. 2. Shape a piece of copper or brass as shown in Fig. 3. Make a cross piece to fit this, Fig. 3a. Fasten the support to the under side of the top, Fig. 4. This part of the apparatus works the same as the adjustment of the E. I. Co.'s electrolytic detector. Examine Fig. 4 carefully and all will be clear. Make a thumb screw as described in November, 1910, issue of *Modern Electrics,* page 452. The top may now be put in place with glue, and is shown complete in Fig. 4.

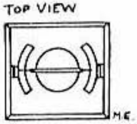
Next we must make a copper cylinder one inch long by one-half inch diameter. Prick or punch two small holes one-quarter of an inch from the top, and diametrically opposite; also two one-sixteenth of an inch from the bottom. These are for the magnetic needles. Cut two slats in the top one-eighth of an inch deep and (wide enough to receive a small mirror, size ¾x½ inch), diametrically opposite.

Magnetize two needles or small bits of steel about one to three-quarters of an inch long. Place one of these in the top holes of the copper cylinder with its north pole to the left. Now place the other needle in the bottom holes, with the north pole to the right. This is to prevent the earth's magnetic field from affecting the readings, and is called the astatic system. The needles may now be fastened with a drop of glue or shellac. Now cut a mirror, ¾x½ inches, and fasten in the slots (on the top of the cylinder), with glue. Fasten a small silk thread to the center of the mirror with a drop of glue, and the other end of the thread must be fastened to the small hook on the plunger, Fig. 7. The spring on the bottom of Fig. 7 is made of No. 40 copper wire which has been annealed, one end being fastened to the copper cylinder and the other end to the base with a small tack.

Now make two coils, each two inches long by one inch wide by three-quarters of an inch thick. Wind them in the form of an arc as described by Fig. 6. They should be wound on pasteboard forms, and wound with fifty feet each of No. 36 wire. The resistance will then be approximately 100 ohms. They should be fastened to the sides of the box, with two pieces of wood as shown in 6a, and connected in series. The other ends are brought on the outside, to binding posts; see Fig. 7.



-FIG. 7-



-FIG. 8-

Now make a back and front from a piece of plain glass and fasten the front so that it will be removable. Fasten a dial on two pieces of wire so that it will be adjustable and finish instrument with several coats of shellac.

Fig. 7 shows a side view of the instrument, and Fig. 8 shows a view from the top.

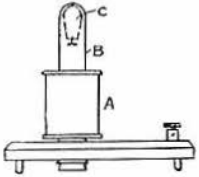
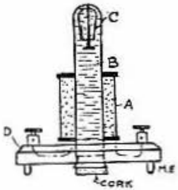
FRANK L. BUNKER.

HOW TO MAKE A GALVANOSCOPE.

A galvanoscope for detecting small currents of electricity can be made from a coil of wire, A; a glass tube, B, full of water; a core, C; and a base, D; with binding posts as shown. The core, C, which is made of iron and cork is a trifle lighter than the water it displaces, and will therefore remain in the tube normally; but as soon as a current of electricity passes through the coil, the core is drawn down out of sight. The current required is very small as the core is so nearly balanced that the least attraction will cause it to sink. The glass tube may be a test-tube as shown in Fig. 2, or any empty





developer tube. If one has neither a test-tube nor a developer tube, an empty pill bottle may be used. The washers at the end of the tube may be fiber, hard rubber, or wood. The base is made of wood, or any other insulating material, and should have four legs on bottom. Make the coil of about No. 18 wire, and connect ends to binding posts as shown at Fig. 2. The core is made by pushing a small nail through a piece of cork. It should be made so as to rise slowly when placed under water. Some filing may be necessary to get the weight just right, but it should be remembered that the buoyancy of the core can be adjusted after the parts are assembled by pressing the cork in the bottom of the test-tube. This causes compression in the water space and especially of the upper cork, reducing its displacement and causing it to sink. The lower cork is then slowly withdrawn, by twisting until the core slowly rises. The instrument is then ready for use.

Connect the binding posts to a single cell of battery—any kind will do, as a slight current will answer. On completing the circuit the core will descend; or put in a switch or push button on one of the battery wires. If the button be concealed where the operator can reach it, the core will obey his command to rise or fall, according to his control of the current. This is a mysterious-looking instrument, the core being moved without visible connection to any other part. If this instrument is connected up as per directions, one will have a very nice looking galvanoscope.

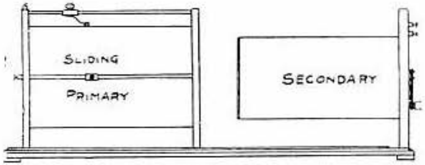
ETHAN CLARKE.

A SIMPLE LOOSE COUPLER FRAME.

As a great many experimenters wish to build their apparatus as simply, cheaply, and with as few parts as possible, I will endeavor to outline a coupler that is simply a "fool killer."

We will start with the base: Procure a well seasoned cherry board 8 inches wide, 20 inches long, and three-quarter inch thick, and cut a slot one inch wide and 16 inches long in the middle as in Fig. 2 A. File this slot perfectly smooth and get two strips of aluminum or brass, 15 in long, one-half inch wide, and one-eighth inch thick as at B. Drill five holes in each and countersink for No. 6 screws. Fasten these strips, one on each side of base and about two inches from slot, and one-half inch from back end of board. After this is done, make two pieces of wood 8x½x1 inches and screw them on the bottom of base at each end as at B, B, (Fig. 2 B). These will keep base from splitting or warping.

Make two pieces 7x7 inches and one-half inch thick, as at a Fig. 3; center them, and cut a hole five inches in diameter through each (or the diameter of your primary tube). Glue one of these boards on each end of tube, and wind on your wire.



-FIG 1-

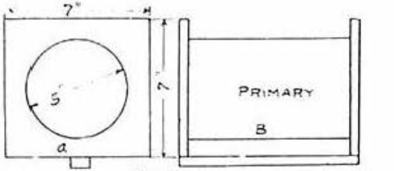
b
SLOT SAWED IN BASE 1" WIDE 16" LONG
c
20"
ALUMINUM CLEAT X
b
B
CLEAT ON BOTTOM
HL

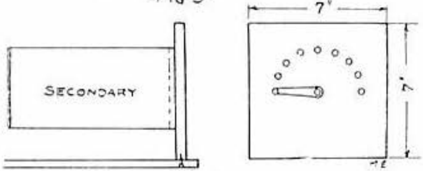
-FIG 2-

After your winding is completed, fasten a cleat on bottom of primary heads, one inch wide, three-quarter inch deep, and eight inches long; this is to slide in groove of base.

For your secondary, make a board 7x7x½ inches, and then cut out a piece four inches in diameter, (or to fit inside secondary tube), and fasten with a screw and some glue in center of head board. Now glue the secondary tube to the head board and make windings, taking off taps so as to use a switch on head of secondary. Fasten the secondary head with screws one-half inch from end of base, X. The instrument may be finished to taste.



-FIG 3-



-FIG 4-

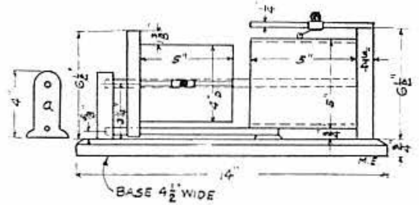
I think that Fig. 1 will make all other points clear.

Contributed by

F. W. DOTY.

A LOOSE COUPLER.

First procure a piece of maple four feet long and seven inches wide. Work this until it is 7½ inches wide and three-quarter inch thick. From this piece cut one fourteen inches long. This is to be the base. Plane a three-eighth inch bevel on this piece. Now cut two pieces; one to be 6½ inches square, the other to be a little less than 6½ inches on two edges and 6½ inches on the other two sides. Now have a piece of white pine turned on a lathe until it is five inches long and five inches in diameter. Hollow this out for a distance of four inches and leave a rim one-quarter inch thick around it. Turn out another piece of pine four inches in diameter and five inches long. Glue these pieces to the ends which are 6½ inches and 6½ by 6 7-16 inches respectively. Now get a steel rod 11¼ inches long and pass it through both cylinders until it reaches the end of the large cylinder. Now bore a one-quarter inch hole in the small piece "a" until it is one-half inch



deep and 3¼ inches from the base. Fit the large rod into this. Now take a smaller piece of rod six inches long and bore a hole in the end of the small cylinder, five-eighth inch from the base. Bore another hole in the end "a," one-half inch deep. This rod is to keep the end of the small cylinder from sliding and rubbing the base.

Now screw the piece "a" to the base and assemble the parts. Then screw the end of the large cylinder also to the base. Now insert a small piece of wood under the smaller rod to hold it in place. Wind the large cylinder with No. 22 enameled wire and the small cylinder with No. 28 enameled wire. If a standard E. I. Co.'s slider and rod is used, the secondary slider and rod will clear the primary coil and allow adjustment while the secondary coil is in the primary. Procure two binding posts for both primary and secondary; each one being connected to a slider and the end of the wire which is nearest to the end of the core, respectively on both coils.

This instrument, when given a mahogany stain and polished, not only makes a useful piece of apparatus, but an ornament to any wireless experimenter's table.

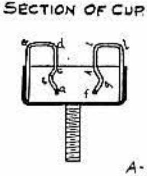
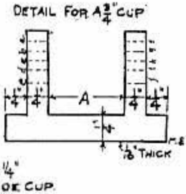
WALTER LEAN.

MINERAL CLASP FOR DETECTORS.

The accompanying sketch shows a clasp to be used in connection with a wireless detector mineral cup.





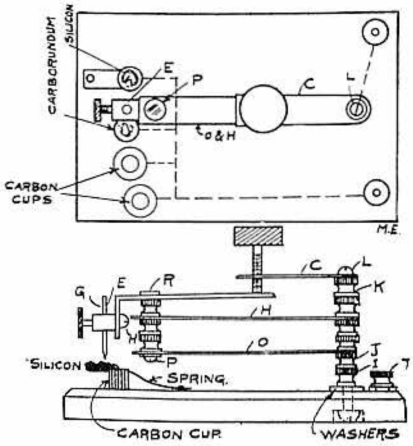
Contributed by

HAROLD W. THOMPSON.

MULTIPLE DETECTOR STAND.

While looking over June, 1910, issue of *Modern Electrics* I saw a detector designed by E. E. Ely.

I started to make one, but changed it so I could use it for more than one stand, by putting two carbon cups on two brass springs, an equal distance from the center bolt L (as in diagram). By this means you can bring either silicon, carborundum, tantalum or electrolytic into use without the aid of a detector switch.



This saves making a switch and more than one stand.

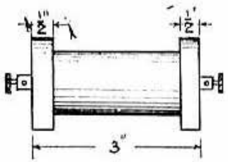
RECEIVING CONDENSER.

A cheap, yet neat and efficient, receiving condenser, can be made from the following:

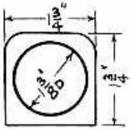
Two pieces of wood (preferably hardwood), 1¾x1¾x½ inches (Fig.

2); nickel-plated shaving-stick box, 1⅜ inch diameter, (Fig. 3); two screw-bottom binding posts, (Fig. 5); section of broomstick 2½ inches long; five sheets of tinfoil, 1¾x12 inches between six sheets of waxed paper that are free from flaws, 2¼x13½ inches.

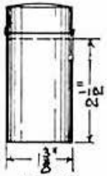
Cut out the wooden ends, centre them, and after having drilled a hole one-eighth inch diameter clear through and rounded the two upper corners, draw a circle with a diameter of 1⅜ inches on the inside of each end, and with a bit or a gauge cut away the wood inside the circle half way through each of the ends; then give them a couple of coats of shellac or varnish (Fig. 2).



-FIG. 1-

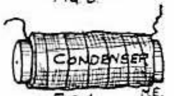


-FIG 2-



-FIG. 3-

-FIG 5-



-FIG. 4

Cut the bottom out of the shaving stick box, and make another cut 2½ inches above, leaving a nickel-plated tube 2½ inches long; then from a broomstick cut a section 2½ inches long; center the ends and start a hole with a gimlet.

Heat the waxed papers containing the tinfoil and then wrap around the wooden core, securing with a few wraps of cotton, being sure that a terminal of the condenser is free at each end (Fig. 4). Insert the condenser into the nickel-plated tube, place the terminal that protrudes from each end into the small holes in the ends of the wooden core; then fit the wooden ends on the tube, and through the holes bored through these ends insert the binding posts and screw into the wooden core to hold the wooden ends in place and make contact with the condenser terminals. (Fig. 1).

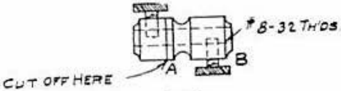
Contributed by

HOLLY STARTZMAN.

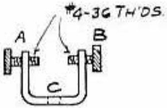
A SILICON DETECTOR.

Silicon is generally a very hard substance to get into adjustment, and once there, is easy to get out of adjustment again. The following will give an idea of my own, how to get rid of both of these troublesome faults of Silicon. This will make an efficient detector at a very low cost.

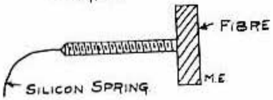
For the base, procure a piece of fibre 2½x2x⅜ inches. Polish it with a file and sand paper and bevel the edges, just for appearance's sake. Then drill two holes, 1½ inches apart the long way of the base and in the center of the distance across.



-FIG. 1-

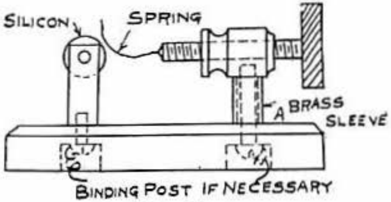


-FIG. 2-

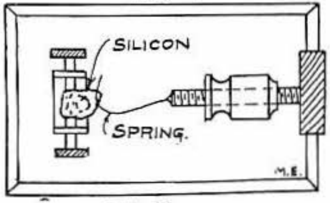


-FIG. 3-

Now get an old double connector (Fig. 1) and cut off about one-third of it at A (Fig. 1). Tap the hole in the center for 8-32 thread. Of course, one of the holes at the end, where the set screw was, (B Fig. 1), should be left.



-FIG. 4-



-FIG. 5-

Now take a brass sleeve that fits the 8-32 thread snugly and place it over an 8-32 screw which passes up through one of the holes in the base (A, Fig. 4). This is to hold part shown in Fig. 1, one-half inch off the base.

For the holder for the silicon, take a piece of brass and bend it into shape (Fig. 2) and thread it at A and B (Fig. 2) with 4-36 threads, to hold the silicon. It is held to the base by a screw through the bottom of the holder at C (Fig. 2).

Now get a brass machine screw 1½ inches long and make a suitable handle for the end of it. Then get a piece of silver or brass (silver preferred), and get a jeweller to roll it down to No. 33 and cut a piece 1-16x1½ inches and solder it on the end of the machine screw (Fig. 3). Then bend it as shown.

The silicon can be placed in the holder and this spring set up against the silicon so as to form a medium contact with it and thus get your adjustments. You should try to use a sharp or fairly sharp edge of the silicon to set your spring up against.

I have found that this beats all the kinds of detectors I have tried. This detector ranks even above the perikon or electrolytic, I think. And with it and suitable apparatus I have heard Honolulu, 2,100 miles away, as well as 1,000 miles over land every night.

Other minerals such as ferron, pyron, etc., can be used in it to good advantage.

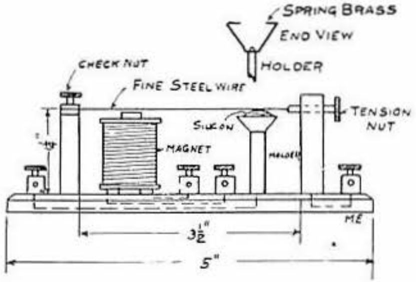
Contributed by

CLARENCE BALLARD.

A Silicon Ticker.

ANY wireless operator living near one of the New Poulsen Wireless stations, doubtless has trouble in reading them, and perhaps he can not receive their signals at all.

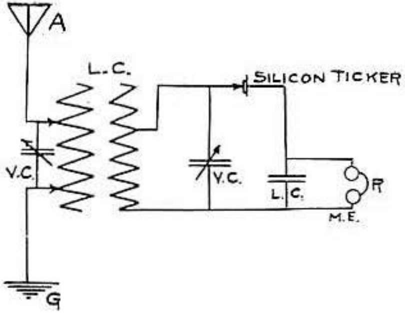
If you live near such a station and have a detector known as a "Silicon Cat-whisker Detector," gently pull the steel wire off and then let it fall back on the silicon; and as it vibrates it will give forth a beautiful, clear, humming sound; like picking a guitar string. This only lasts for an instant; as long as the wire vibrates against the silicon. From this experiment I worked out the following instrument which gives the result which the Poulsen people say can only be accomplished by their instruments, i. e., the Poulsen "Ticker."



The base is made of hard wood or rubber one-half inch in thickness, five inches long and 3 inches wide.

The small bell magnet can be taken from any electric bell of convenient size; generally they are one one-eighth inches long; the dimensions on the diagram being for this size. If you have a different size the dimensions must be changed so the magnet will always be one-eighth inch away from the steel wire. This wire is the E string of a mandolin and must be steel. Make two brass standards one one-half inches long and drill holes in them one one-quarter inches from bottom, as in diagram, then thread in from the top for the check-nut on one of them, and on the side of the other for the tension nut. The tension nut can be taken from the spring of an old telegraph sounder; this is to keep the wire from breaking by twisting around.

Distance between standards is three and one-half inches. The electro-magnet is mounted exactly one-eighth inch under the wire. The holder is also mounted under the wire, so the wire will strike the top surface of the silicon. End view of holder is shown in Fig. 1.



Binding posts should be screwed on the ends of the ticker. One goes to the standards and one to the silicon holder; also two in the middle for the magnet.

The magnet is connected to the alternating current supply, preferably 110 V. A. C. through a resistance which can be varied. Not more than four volts should pass through the magnet or it will heat up. A small water rheostat works very well in this connection. A small switch should be mounted near the ticker to open the circuit when you are not using it.

The ticker is connected up as in Fig. 2. The condenser which shunts the phones is three times as large as an ordinary condenser used in wireless work. The variable condenser should also be used to get good results.

Now adjust the tension nut and vary the current in the magnet, and tune very closely for what is known as the "Conversation Wave" and you will be a surprised person.

These stations send out two separate trains of waves. The arc sends out a sound which sounds like spilling milk, but you must tune for the waves which are generated in the closed oscillation circuit, arc, condenser and inductance. The station in question has an immense fan aerial composed of thirty-seven wires stretched between two 300-foot towers, 400 feet apart. They talk daily with a station in Texas.

Contributed by

STANLEY HYDE.

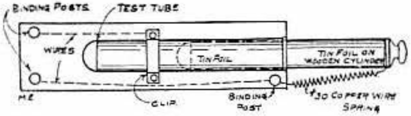
A SMALL VARIABLE CONDENSER.

Procure a chemist's test-tube six by seven-eighths of an inch in diameter. Coat the outside with shellac, and when nearly dry apply one turn of tinfoil. This forms one surface.

For the other surface take a wooden rod a trifle smaller than the inside of the test tube and about seven inches long. Cut a knob on one end to facilitate the sliding. Build this rod up with tinfoil until it barely slides into the test-tube.

For the clip use a piece of aluminum one-half inch wide and three and a half inches long. This will serve to hold the test-tube to the base, which is 8x2x½ inches, and also to make connection to the tinfoil.

By referring to the diagram you can see how the other surface is connected



to the wires. The wire is scraped bare for eight inches and then wrapped around the tinfoil.

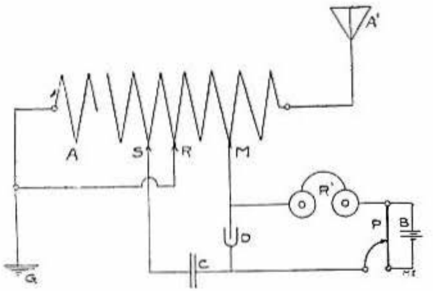
This makes a very efficient condenser and has a capacity of about .001 M. F.

Contributed by

N. E. DORRINGTON.

THREE SLIDE TUNER.

If one is making a three slide tuning coil and does not know how to operate it, or for some reason would like to change from a three slide tuning coil to a one or two slide, one can do so by adding the following:



A'
A
S
R
M
R'
D
P
B
C
G
H E

When your coil is almost finished winding cut the wire about one inch from the end, then add a separate winding, A, and ground as shown in drawing.

To operate as a two slide tuning coil move slider, S, to winding, A, and then only slider, R and M, are in use.

To operate as a single slide tuning coil, move sliders, S and R, to winding, A, thereby using only slider, M.

To operate as a three slide tuning coil move sliders off from winding, A, thereby putting them all in use.

This will help one to adjust a three slide tuning coil also to experiment with single and double slide coils.

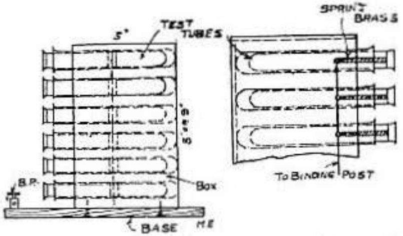
WILLIAM McGUIRE.

AN EASILY CONSTRUCTED VARIABLE CONDENSER.

THE following is a description of my variable condenser which was constructed at home, very cheaply and easily.

First procure twelve glass test-tubes, six of them 6x1 inch, and the other six of a size that will just slip inside these. Cover all the tubes with tinfoil, on the outside only, and make the inside ones fit very snugly, as the closer the tinfoil surfaces are together, the more efficient the condenser will be. Next get a box, eight or nine inches long and five inches wide by one and one-half inches deep. A cigar box with the lid nailed down and one side taken out will do very well.

Connect the large tubes with a piece of bare wire, making two or three turns around each one, to insure good connections. Space them about one and one-half inches apart. Leave four or five inches of wire to connect with the binding-post.



Now place the tubes in the box and run the wire through a hole in the bottom. Fill the space around them with melted paraffine and space them carefully before it hardens.

The connections to the movable tubes are made of strips of thin spring brass. They should bear pretty hard on the tubes. If the box is stained black and given a coat of shellac, it will be a very good looking instrument.

Secure this on end, to a base about 3x8 inches, and connect the binding-posts. It is then ready for use.

Vary the capacity by pushing jars in or out.

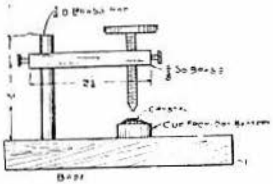
JAMES BITLER.

A SIMPLE ADJUSTABLE DETECTOR.

Any boy with a set of stocks and dies or a machine shop where he can use them can make this detector. It needs no explanation as by referring to the illustration the parts can be easily constructed.



Contributed by

THORNTON KEARFOTT.

ROTARY DETECTOR.

The case is made of ⅝-inch oak. It is 2 inches deep, 6 inches wide and 4 inches high. A small window is cut in the front at the top to inspect the contact. On top a large thumbscrew turns in a brass plate, to make contact. On the front there is a knob and pointer which will indicate what mineral is being used.

The wheel which the minerals are placed on is made of a strip of copper (Fig. 2). Small brass cups which hold the mineral are soldered to this strip. This is then tacked around a wooden disc, 3 inches in diameter. Through this disc the shaft is placed which turns in the front and back of case for bearings. A copper strip is tacked to the bottom of the case, inside, which makes contact with the strip on the wheel. Connections are made from this strip and from the brass plate on top. The drawing will make the description more clear.

RAYMOND RUTHERFORD.

VARIABLE CONDENSER.

The first thing to do is to obtain four pairs of handles from a medical coil. These may be obtained from almost any electrical house or from your friends who are equipped with medical batteries.

A piece of hard wood or fibre seven inches by six, and about half an inch thick will do for the base. Another piece of wood seven inches by two inches and half an inch thick will do for the upright shown in Fig. 1.

Now bore four holes in the upright, 1½ inches from the bottom and 1 3-16, 2 13-16, 4 5-16 and 5 15-16 inches from the end. These holes should take an 8-32 machine screw.

Screw the upright to the base and we are ready to use the electrodes. Remove the screws from each end and insert 8-32 battery screws through the holes left.

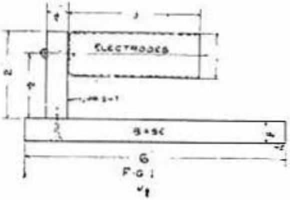

FIG 1

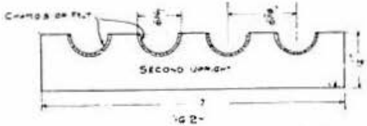

FIG 2

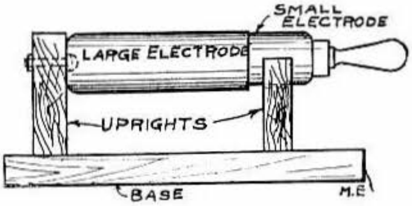
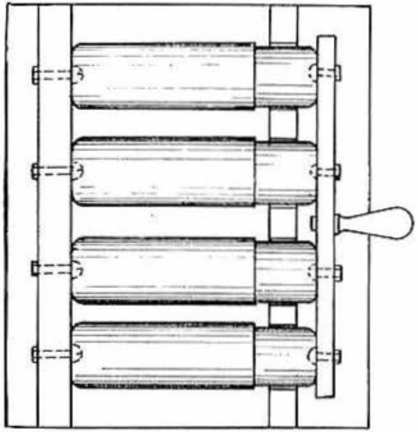
The four larger electrodes may now be clamped to the upright and the latter fastened to the base as in sketch. The four nuts may be connected by a piece of sheet brass or thin wire.



-FIG. 3-

Dip the four smaller handles in thick shellac and let stand till dried. A brass bar six inches long three-quarter inches wide and one-quarter inch thick is now clamped to the four smaller electrodes



in the same manner as before. A handle may be fastened to the bar to facilitate its use. An upright is made of wood as in Fig. 2 and fastened to the base. Two binding posts complete the instrument. The movable electrodes should be connected to the binding posts and instrument should look like Fig. 3. A high polish on all wood and brass parts gives it a very handsome appearance and any amateur may well be proud of it on his instrument table.

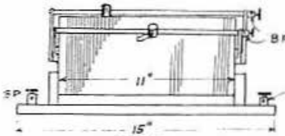
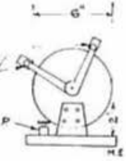
STANLEY F. PATTEN.

A CLOSE COUPLED TUNER.

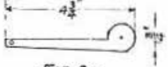
We have herewith the plans for a very close tuning coil.



-FIG 1-



-FIG 2-



-FIG 3-

The coil is wound with No. 22 bare copper wire, and in such manner that the wire does not touch the next wire in any instance. (This can be done by winding a thread between the wires.) The brackets are put on so that they will move, but not enough that they may fall of their own weight. The connections are the same as any other double-slide tuner.

With this coil very sharp tuning can be done and it also replaces the small tuner usually used for sharp tuning.

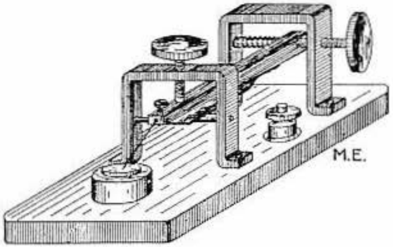
HAROLD WOOD.

GALENA DETECTOR

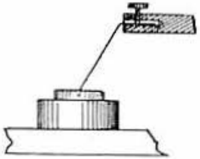
The drawings herewith are intended to illustrate a detector I constructed recently, which, after testing, I think will be welcomed by the amateur who still adheres to the mineral type of detector.

One great fault I find with the average detector is that the up and down adjustment of the contact is not sufficient to find the sensitive spot in the mineral; and if the adjustment is made by sliding the cup around it is liable to get out of adjustment at the least jar.

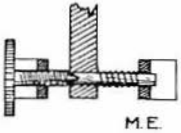


The adjustment of my detector is very delicate; and to use it, first adjust vertical thumb screw until wire just touches mineral, then turn side thumb screw, drawing the contact wire sidewise over the mineral until a spot is found. If all goes well, and a good piece of galena is used, a large station will come in like thunder.

The contact wire may be No. 30 to 36 platinum or copper (I prefer platinum). Manipulating the top thumb screw gives a front and back adjustment to the contact point. This, together with the side thumb screw, permits



Detail of Contact with Crystal.



Construction of Rear Pivot.

any point on the surface of the crystal to be reached. The cup is fixed in position, but may be revolved.

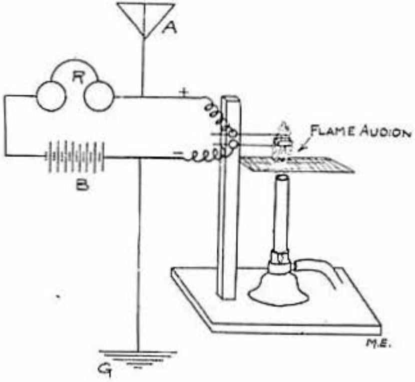
J. F. ARNOLD.

A FLAME AUDION.

The Audion as a receptor of Hertzian waves seems to have lost a place in the heart of the wireless experimenter. However, the following may interest a few, because it provides a good field for investigation. The object of all audions, is to get one of two terminal plates to throw off ions, which act as a relay to high-frequency oscillations that pass between the plates.

Bunsen burner is used to furnish the flame, A, and salt or any alkaline metal in the flame produces the ions. The salt is contained in a small trough of platinum, which is easily made by flattening and shaping a piece of platinum wire, since the trough is only three-eighths of an inch long and one-sixteenth of an inch wide. About one-sixteenth of an inch above the trough is placed another piece of platinum wire. The trough is the cathode of the telephone circuit and the wire the anode.



This detector is so sensitive that the least flicker in the flame is registered as a sound in the receiver. So in order to produce a steady flame, a wire gauze is placed just above the burner, then, the flame produced is extremely steady. However, it should be provided with a mica chimney to protect it from the air currents.

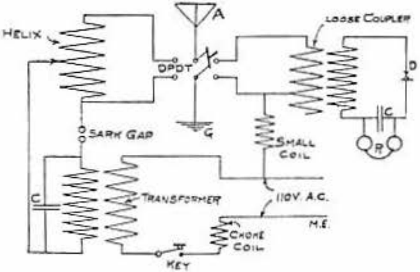
The sketch explains the arrangement and construction. The base and pillar are made out of wood, or better still hard rubber. Binding posts are fastened to the pillar to take the trough and wire.

Eight dry cells, connected to a multiple point switch so that any adjustment from 4 to 12 volts may be secured, are placed in series with the detector and receiver. By keeping plenty of salt in the trough and carefully adjusting the voltage, a marvelously sensitive detector may be made.

Contributed by

MEARLE MELLINGER.

I have been an experimenter in wireless for about three years. During that time I have been bothered with a continual hum in my phones.



I have finally, after trying many ways, succeeded in stopping this hum without decreasing the signals in the least, and if anything, increasing them.

The drawing will explain itself. The coil does not have to be of any particular design, although I used an old tuner, wound with No. 24 S. C. cotton wire. I also find that it will cut out static to a certain extent.

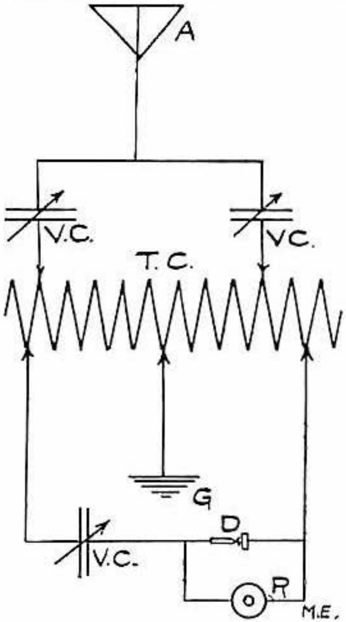
HARRY KING.

ELIMINATION OF INDUCTANCE DISTURBANCES.

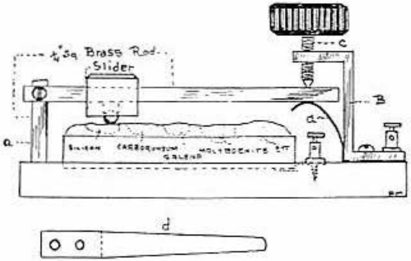
A clever method has been suggested and found to be successful in practice, for the elimination of sounds in telephone receivers, produced by neighboring power lines. This method, set forth by S. G. Brown, the well-known British wireless investigator, is shown in the diagram which is self-explanatory. A five-slide tuning coil, three adjustable condensers, detector, and telephone receivers are necessary. Probably a three-slide tuning coil will fulfill the purpose if the end connections on the coil are used in place of two of the sliders.



UNIVERSAL DETECTOR.

An improvement over Mr. Hutchinson's detector in the May issue of *Modern Electrics* is shown in the illustration.

Instead of fixing the slider rod on two brass uprights it is pivoted on a bar, A, at one end, and at the other end is provided with an adjusting mechanism. This consists of an aluminum bracket, B, the kind E. I. Co. use on the "Electro"-lytic detector, and a thumbscrew, C. Before screwing the bracket, B, to the base, a spring, D, is cut from a one-sixteenth



inch sheet brass, and drilled as shown. It is then fastened under bracket, B, as shown.

This spring is used to keep the slider rod up against the screw, C.

P. MERTZ.

ANOTHER VARIABLE CONDENSER.

Enclosed herewith are some drawings that perhaps will interest some of your readers, on a variable condenser which I am using with good results. It is a fine looking apparatus when polished and finished, besides easily operated.

The wood is made out of oak, three-eighth-inch stock, and polished or stained with mahogany dye. The contacts are made of German silver and the knobs are from a typewriter which can be gotten at any typewriter store. The condenser is made of tinfoil and paraffined paper, being sealed in wax after all connections are made in the base. The brass tube can be cut with tin shears and the edges filed until the contacts slide on easily.

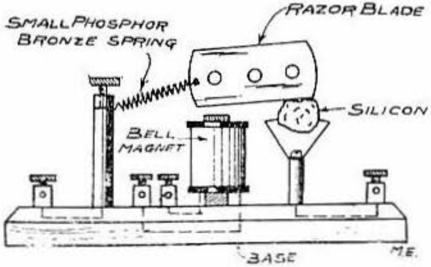
IMPROVED SILICON TICKER.

The following apparatus is an improvement on the ticker described by the writer on page 88, May issue of *Modern Electrics.* I have been waiting to see an improvement appear in *Modern Electrics* on this piece of apparatus but am disappointed; evidently not many experimenters having used it.

The improvement consists of soldering an inch or more spring phosphor bronze one-eighth of an inch wide to an ordinary Gillette safety razor blade which is very flexible and has sharp edges to make contact with the silicon. The blade should be about one-eighth of an inch above the bell magnet. It should rest gently on the silicon. The rest of the ticker is constructed the same as the first one described in the May issue.

The advantage in this form is that it is very much easier to adjust and holds its adjustment indefinitely. It can also be used to receive ordinary spark signals by simply cutting off the A. C. current. Using it this way it is very much better than a so-called "cat whisker detector." The Poulsen people



SMALL PHOSPHOR BRONZE SPRING
RAZOR BLADE
SILICON
BELL MAGNET
BASE
M.E.

have certainly "got one over" on the spark systems.

The station in this city keeps up unbroken communication with El Paso when the United Wireless and amateurs are sending within a few blocks' radius. They cannot hear spark stations unless they connect on an ordinary receiving outfit, which they sometimes use.

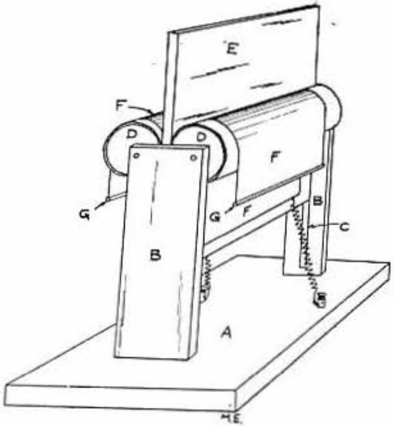
STANLEY E. HYDE.

A NOVEL CONDENSER.

This variable condenser is quite convenient to use in connection with a semivariable condenser where the glass plates are very large, as after cutting in or out the proper number of plates, the adjustment may be brought to a very fine point by moving the movable glass plate up or down.

The construction may be clearly seen in sketch.



A is suitable wood base. B. B. are wooden uprights with grooves, C, on the inner sides. D. D. are wooden rollers—pieces cut from a curtain pole are excellent—covered with felt or several layers of soft cloth. E is glass plate of proper size to move freely in grooves, C. F. F. F. is tinfoil an inch less in diameter than the glass used. G. G. are metal rods to counterbalance the glass plate.

Fasten the rods used for counterweights to one side of each piece of tinfoil and then glue the opposite side of each piece along a strip of one-half inch on opposite sides of glass plate, the right distance from edge, and next give the rest of the plate that is to come in contact with the tinfoil a coat of petroleum jelly and the plate is ready to insert between the rollers, as shown in sketch.

The rollers must work smoothly and press tinfoil and plate firmly together. After adjusting plate connect a piece of fine wire, coiled spring fashion, to tinfoil on each side and opposite ends of plate and bring the other ends down to two binding posts on base and the condenser is complete.

To operate push plate down or pull up, thereby causing tinfoil to adhere to or strip from plate, till the point for best results is found.

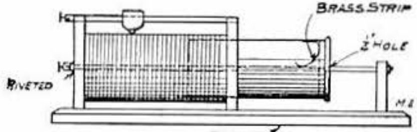
R. S. TRUE.

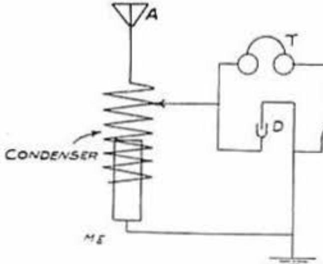
A NEW TYPE OF VARIABLE CONDENSER.

Here is a new kind of variable condenser which is very effective in cutting out static and high voltage line interference.



-FIG 1-

Materials required: One brass rod ¼x8 inches, 1 thin brass strip ¼x2½ inches, 1 slider to fit, 1 mailing tube 3x7½ inches, 1 brass mailing tube 2¾ x7 inches, 1 fibre end for small tube ½ inch thick, 2 block ends 4x4 inches, 1 base 5x16x½ inches, 1 brass tube 14 x¼ inches, 1 brass rod ⅜x1⅞ inches,



-FIG 2-

1 brass rod machine screw about 14-20 inch round head, ½ pound No. 18 bare copper wire.

Assemble the parts as shown in diagram. Connections are also shown in Fig. 2. A quarter inch hole is drilled in one of the binding posts to fit the tube.

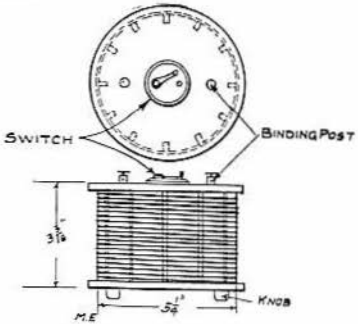
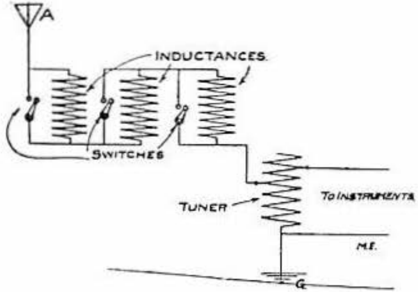
LAWRENCE KREIDLER.

AN INDUCTANCE OR LOADING COIL.

Sometimes when you want to listen to a high powered station like Glace Bay you find that the wave length of the station is greater than the combined wave length of your antenna and tuning coil. If, however, an extra coil of wire is placed in the aerial circuit, the wave length is considerably increased.



To make this extra inductance coil, procure several wooden spools such as annunciator wire comes on, several hundred feet of enameled wire No. 22, B. & S. gauge, and five or six large binding posts. The spools will be found to measure about 5¼ inches in diameter by 3 3-16 inches high; this will allow about 55 turns of wire 18 inches long, the turns being nearly 1-16 of an inch apart. Cut 16 pieces of hard wood 3 3-16 inches by ⅛ inch by ¼ inch, round the corners with a knife, and fasten around the circumference of the spool with 1 inch brads equal distances apart. The completed frame should be given a couple of coats of varnish and allowed to dry before winding on the wire. Wind 55 turns of wire on, with the turns about 1-16 inch apart. Fasten two binding posts on the top of the coil and connect the two ends of wire to them. Over the hole in the center of the coil head place a battery switch (1 point) to be used for shorting the inductance when not needed; connect one pole of the switch to each binding post. Give the whole coil a coat of varnish and while still wet place a piece of thin rubber around the wound part. This gives a finished appearance to the coil and helps to keep the wire in place. Mount on small porcelain knobs.



If your aerial and tuner are small several inductances may be required, and all must be connected in series.

For details and wiring diagram see the drawings.

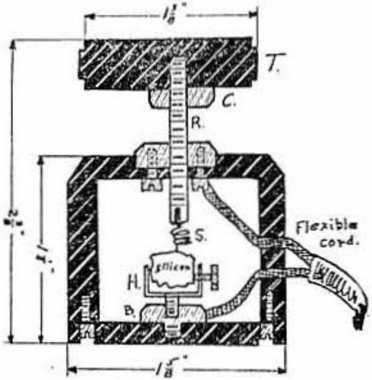
R. S. CRAWFORD.

ENCLOSED COMBINATION DETECTOR.

The detector described in this article has been tried out on long distance receiving and holds its adjustment admirably. All parts can be made on a small lathe with little trouble.

Fig. 1, is a sectional view of the detector. The hard rubber case is turned from a piece of hard rubber 1¾ inches in diameter. The inside diameter is 1⅛ inches. The top edge is beveled so it will not have such a square appearance, the bevel is about 45 degrees. The drawing shows a sectional view of the detector and is approximately full-size, so all the dimensions are not given as you can vary the dimensions to suit yourself.



Cross Section of Detector.

The thumb screw and the case are turned from hard rubber. You will find the hardest part in turning out the inside of the case; the walls of which should be left at least one-quarter inch in thickness, so there will be room for the small screws that hold the bottom cover on. The cover should be fitted to the case after it has been turned out to the proper size. Rod (R) is threaded with 10-24 die, as well as the bottom part of the crystal holder. Check-nut (C) is screwed on to the rod to help out the appearance and also brace it on tighter to the thumb-nut.

Great care should be taken in threading any of the rubber parts as the tap is apt to break the threads if screwed in too fast. On the end of the rod is soldered a comparatively fine steel spring wire that fits in a small hole bored in the rod. Holder (H) is made so it can hold any mineral by the use of the screw which clamps it in place.

Finished Detector.

Two holes are bored in the side of the case so as to let two leads of a flexible cord pass through, which are soldered, one to the small screw which holds the rod in place, and the other to the bottom of the crystal holder. The finished rubber case can be then buffed up and made to look very attractive.

The photograph gives a much better idea of the appearance which this detector gives when it is finished. It is capable of very fine adjustment and can be used for any crystal. The length of the cord is made to suit the needs of the user, being in this case one foot long.

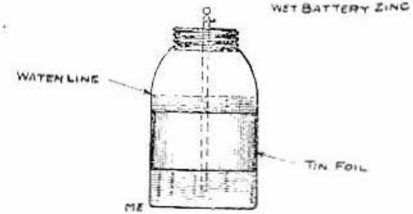
STANLEY E. HYDE.

FIXED CONDENSER.

Herewith find a sketch of a fixed condenser, which I think will be very efficient in wireless work.

It will require a one quart fruit jar and a strip of tinfoil 3 inches wide and long enough to go around the jar, and a wet battery zinc. Remove the glass from under the can cover and bore a hole in the top of the cover, next fill with water up to dotted line on sketch, add a teaspoonful of salt to the water. The sketch will explain the rest.



Contributed by

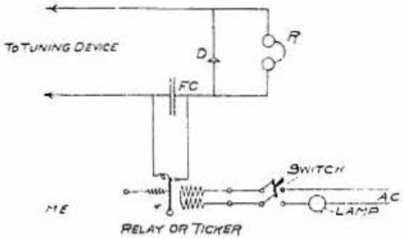
JOHN HOGAN

AN IMPROVED POULSEN TICKER.

For all operators who are able to hear any of the various Poulsen stations in the United States, an efficient "Ticker" will prove of considerable pleasure and interest. The "Ticker" to be described is very simple of installation and operation.

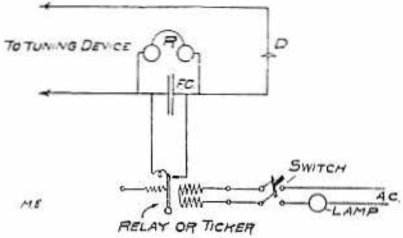
A low resistance telegraph relay comprises this "Ticker." This may be purchased new at any supply house from three to four dollars, and second hand, for very much less.

The magnets of the relay are connected to any alternating current source of electricity in series with a 16 c.p. lamp and suitable means for making and breaking the circuit. The other two binding posts on the relay, which are connected to the platinum contact points, are connected to the two sides of the fixed condenser in the receiving circuit. Two different hookups are shown below.



-FIG. 1-

Whenever the familiar frying of the Poulsen arc is heard, the "Ticker" should be switched onto the A.C. mains, and the signals may be read as easily as with the spark system of wireless telegraphy.



-FIG. 2-

This "Ticker" will prove much more efficient than those which are directly connected to the rectifying element in a detector. The moment that the "Ticker" is disconnected from the A. C. current, the set is receptive for spark system signals.

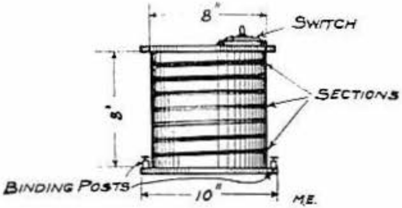
ELLERY W. STONE,
California.

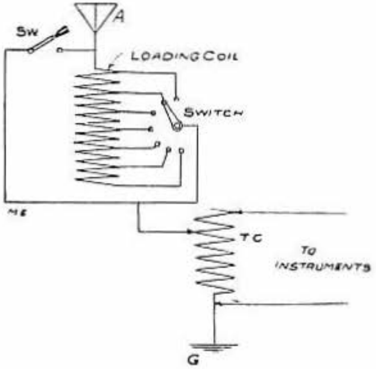
A SIMPLE LOADING COIL.

A simple and efficient loading coil for receiving long waves may be made as follows:

Make a hollow tube of cardboard eight inches in diameter and eight inches in height. Boil the tube in paraffine until the bubbles cease to come from the cardboard. Procure several hundred feet of No. 24, B. & S. gauge enameled wire.



One half inch from the top of the tube start winding the wire and continue winding until a section one-half inch wide has been completed. Break off the wire allowing about one foot for lead and fasten. Measure one-half inch from completed section and wind another section. Continue making these sections until the tube has been filled but a space of one-half inch should separate each section. The lead from each section should be led to a switch and connected as per diagram.



This coil makes a very neat instrument when constructed with care and is capable of getting those high-powered stations with ease.

The coil will be greatly improved if end pieces are added and the switch mounted on one end.

Contributed by
ALLEN DAHLQUIST.

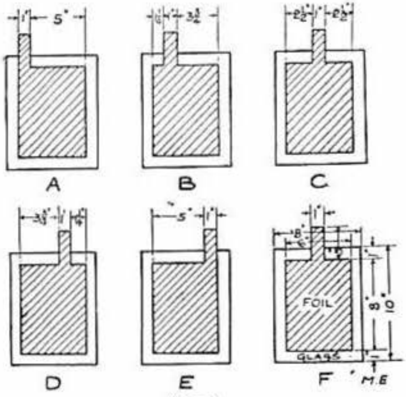
AN OIL CONDENSER.

An authority states that more sending sets prove inefficient through losses brought about by a poor condenser than from any other one thing, losses in some stations amounting to as much as 33 1-3 per cent. of the total energy. Why not save this lost energy by building the condenser right in the first place?

From any large photographer procure 40—8x10 inch used plates. He will give you all that you can carry away. These plates are particularly suited for this purpose as they are absolutely free from flaws of any kind. Clean the plates in hot water and dry them thoroughly. These plates may seem small but they allow the use of six-inch tinfoil, which is much easier to procure than wider sizes.

Between two and three pounds of tinfoil will be needed as the lugs and plates are to be cut in one piece. Cut the pieces 6x8 inches with a lug 1 inch wide and 3 inches long on one end. Alternate these lug ends so that on adjacent plates the lugs come out at opposite ends of the pile of plates. The first lug should be placed as at A. (Fig. 1); the next two as at B (Fig. 1); the next three as at C (Fig. 1); the next four as at D (Fig. 1); the next ten as at E (Fig. 1), and the remaining twenty as at F (Fig. 1).

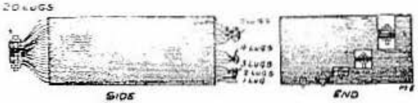
The glass plates should now be thinly coated with vaseline; the plates of tinfoil placed on the glass so as to clear the edges by one inch all around, and the foil rolled tight to the plate. The vaseline makes an excellent adhesive for this purpose, and as it does



-FIG. 1-

not harden all of the air can be gotten out from under the tinfoil. When the foil is all rolled tight coat the whole plate with from one-sixteenth of an inch to one-eighth of an inch of vaseline. Treat the remainder of the plates in a similar manner. Now pile up the plates so that at one end 20 lugs are at the center, while at the other end there are five bunches of 1, 2, 3, 4, and 10 lugs each respectively. These bunches of lugs must come from consecutive plates and be on the same part of the plate. The pile should look as in Fig. 2. Compress the pile and tape it together.

Build a box of oak (⅝ inch stock) 10x14x5 inches (outside measure). Miter or rabbet the corners, glue the bottom on, and fasten the top on with nickeled round headed brass screws. The box may be filled and varnished or just shellacked as preferred. It should be well shellacked inside, however. On one end of this box a hard-rubber or fiber plate ¼x4x9 inches should be fastened. On this plate mount five 15 ampere S.P.S.T. knife switches and two large binding posts.



-FIG. 2-

One end of every switch should be connected to one of the binding posts by a copper bus-bar. The five other ends are connected to the five bunches of lugs 1, 2, 3, 4, 10, in order. The lugs at the other end of the plates are all connected together and to the other binding post.

This about completes the construction. By this arrangement any number of plates from one to twenty can be cut in by closing the proper switches. For instance, if 17 plates were desired, the switches connected to the bunches of 3, 4, and 10 plates would be closed, and so on. The thick vaseline cuts out the brush discharge almost entirely and furthers the general insulation. This condenser was designed for use on any coil or transformer up to and including ½ kw., but any larger size can be built accordingly.

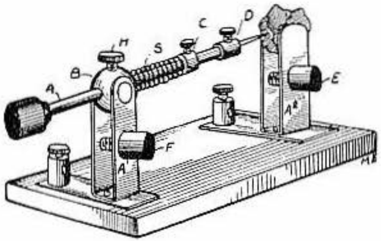
L. W. TELLER.



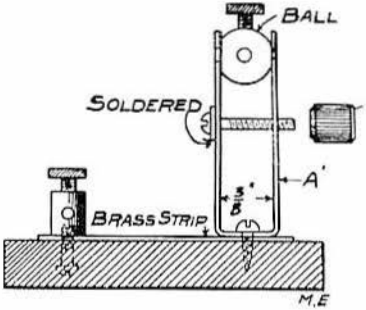
-FIG. 1-

UNIVERSAL DETECTOR.

The parts of the detector are mounted on a hard wood base 2½x3½x½ inches. The edges may be beveled to give a better appearance.

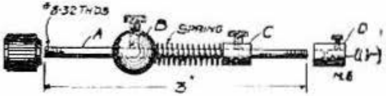
Next make two U-shaped standards (A^1 and A^2) of spring brass, using material ½ inch wide and 1-16 inch thick. They should stand about two inches high, thus requiring 4½ inches of material for each standard. One of these clamps the mineral while the other supports a ½ inch brass ball (B), which is held in place by practically the same method used on the back of wireless receivers, and allows the rod A to be moved in various directions.

By studying the drawings one will easily be able to understand how the detector works. Suppose you want to use a mineral that requires a rather heavy pressure on its surface. Place the mineral in standard A^2 using the knob E to clamp it tight. Thumbscrew H must be loosened so that rod A is able to slide back and forth through ball B. The pressure of the point on the mineral is regulated by the collar C, by changing the tension of the spring S.



-FIG 2:-

All that is necessary now is to place the point on a sensitive spot of the mineral. Silicon, carborundum, and pyron are generally used with the set screw H loose, using the spring S to push the point against the mineral. Galena is an excellent mineral to use.



-FIG.3-'

The detector may be used as a perikon type, by clamping the zincite in A^2 and for the other mineral solder a piece of bornite in a cup having a shank on it, and clamping the shank in the tip D.

The writer has made two of these detectors and mounted them on his receiving cabinet, using a double point switch to change from one to the other. By connecting two detectors this way they may be easily adjusted to the highest degree of sensitiveness, which they possess.

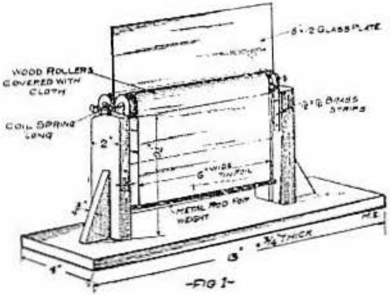
VARIABLE CONDENSER.

In the September issue of this magazine appeared a Novel Variable Condenser contributed by R. S. True, one of which I made and found to be alright, except for the cloth covered wood rolls. I found it almost impossible to get them to run true. When the glass plate was moved up or down rolls would move away from plate just enough to prevent the tinfoil from making a good contact with plate.

So I made a device as shown in enclosed sketch which is composed of four brass strips two on each end of plate ½x1-16x5 inches long, the strips having 3-16 inch holes bored ½ inch from each end, and two small coil



-FIG 1-

springs, one for each end of the condenser. These are slipped over the screws together with the brass strips before the screws are put into the wood rolls. I have found this to give fine results and it works very smoothly when glass plate is moved up or down. As the brass springs hold rolls firmly against plate nearly perfect contact between the tinfoil and the glass is secured. The enclosed sketches will fully describe everything.

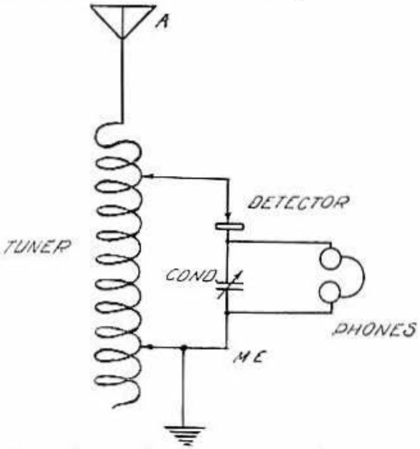
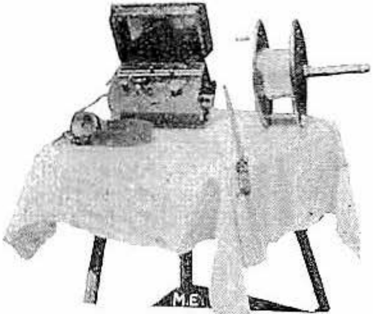
FIG B



A
DETECTOR
TUNER
COND.
PHONES
M E

The first thing to procure is the box for holding the tuning coil, variable condenser and the detector. In this case the box was formerly a medical battery case measuring about 9x5x5½ inches. Excellent boxes of this kind can be purchased from the Electro Importing Co., for a very reasonable price.

The tuning coil is wound with No. 24 enameled wire and is 1½ inches in diameter. It just slips into the case and is held in place either by screws or carpenters' glue, which is very strong. The sliders are the regular hard rubber ball bearing sliders, which are made to fit a ¼ inch brass rod. Care should be taken in scraping off the insulation from the wire where the sliders make contact with it, as the wire is not very large in cross section.



Portable Wireless Outfit.

Th condenser is made up in sections and each one is twice as large as the one preceding, the first one being 10x4 inches. A good way to get these condensers is from a local telephone company. They can be purchased for about 25c. and about 10 receiving condensers can be made from a single telephone condenser. There are five of these and taps are brought out on the case with a switch for cutting in the different capacities, as shown in the picture.

At the left of the condenser is the detector which is shown in Fig. B. The crystal holder (H) is ½ inch in diameter and in this is soldered the silicon crystal or other mineral that is preferred. It is threaded with 10:24 die to fit the holder base (B). It is well to make a number of these holders so that any crystals can be used. An excellent solder that will cool off but will not harden for about fifteen minutes can be made by melting one part mercury with three parts of solder.

Two binding posts are provided on each end of the case, one pair for the telephones and the other for the ground and aerial. The phone is a single one of 1,000 ohms and can be carried in the pocket along with the short head-band.

The spool for carrying the aerial wire is a large magnet-wire spool and measures 9 inches in diameter. It is 3½ inches deep and will carry about 2,000 feet of No. 18 annunciator wire. This wire is very flexible and does not kink easily.

With the connections shown at Fig. (C) the use of a ground connection is determined by the length of the aerial wire. If the wire is very long the use of a ground actually hinders the receiving ability of the set. This is not always the case, but for every 7 stations out of 10 this rule will hold true.

So that if you are out in the wilderness some where, you don't need to worry about a ground connection if you can tie a rock to the end of the wire and heave it up into some high tree and stretch the wire out for about 300 feet.

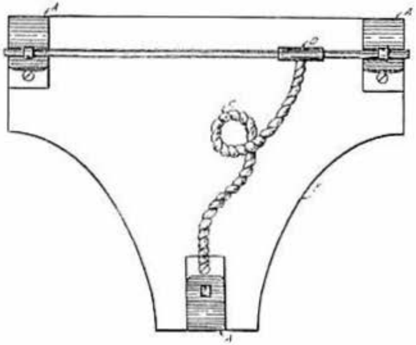
To show the sensitiveness of small sets like this, the writer one morning some months ago, stretched a wire from a tree 15 feet high for about 100 feet across a vacant lot and without any ground heard the (S.O.S.) sent out from the ill fated S.S. Santa Rosa, which went on the rocks near Pt. Arguello during one of the most severe storms ever experienced on the Pacific Coast. Contributed by

STANLEY E. HYDE.

CHEAP POTENTIOMETER.

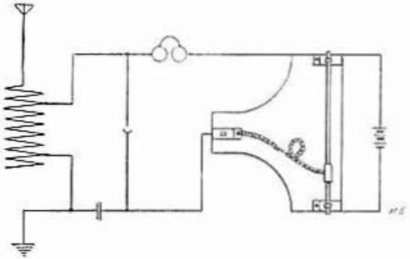
Below is description of an efficient potentiometer.

The base is made of wood (preferably hard wood), size about 8x8 inches, ¾ inch thick.



The graphite rod is taken from a hard lead pencil, it can be taken out by soaking pencil in hot water for some time.

The ends of rod are held in place by inserting ends in spring clips at ends. The contact is made with rod by a short piece of brass tubing, just large enough to slide along easily on graphite rod. To this tubing is soldered a piece of flexible cord, which is fastened to binding post at bottom.



Drawing shows how to connect up for use.

PERIKON DETECTOR STAND.

The following is a description of a "Perikon Detector," which I have been using for some time with excellent results. It cost me exactly $.40, and was made, excluding the base, in twenty minutes. All the material necessary can be purchased from the Electro Imp. Co., and will conform nicely.

The base is of mahogany, 3x5½ inches, and beveled to improve its appearance. If this cannot be procured, a S. P. D. T. switch base will do nicely. The two standards, are double binding posts. The one supporting the zinc crystal is set on two 3-16 inch washers. When fastening it down it should be let a little loose, and a drop of oil be placed between the washers so as to act as a swivel. The other one is set directly on the base. A large brass washer or pillar is next procured; with a hole in it to pass an 8-32 machine screw. It should be ⅝ inch high and ½ inch in diameter. A hole is drilled in the side, just deep enough to get a few 8-32 threads in it. A small piece of threaded brass rod fastens it on the binding post. However, it should clear the top by about 1-16 inch so as to revolve in a semicircle freely. Both the rods are of 5-32 inch brass, threaded 8-32 at both ends. The spring should be rather weak, fine phosphor-bronze wire is best. I think the drawing explains the other points. Fig. 2, is the small piece which allows the copper pyrites cup to revolve in a small arc. It is cut out of 1-16 inch brass sheeting, and the holes bored about ¼ inch apart. The size is dependent on the size of the cup used. The pressure on the minerals can be varied by moving the zincite mineral backwards or forwards. It may take a little while to get used to this de-

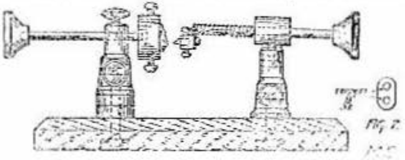

Fig. 2

tector, but it is very sensitive, and there is no possible adjustment which cannot be made; it being possible to reach every point on the zincite. Also, when sending, instead of shorting the detector, the minerals are disengaged, thereby saving them from being burnt out.

Contributed by

GEO. W. KELBY, JR.

CRYSTAL MOUNTING.

As most experimenters know, soldering takes a good deal of the sensitiveness away from the mineral, and tinfoil wads no matter how tightly packed, do not hold the crystal firm. Wads of fine copper wire (34-36 B. S.) jammed between the crystal and the cup hold it firm and make a good contact.

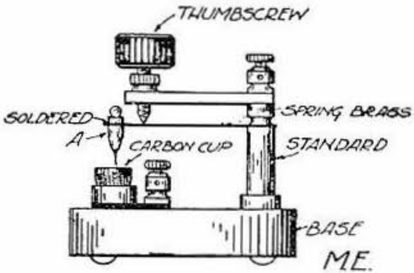
VAN ALLEN TREAT.

IMPROVED ELECTROLYTIC DETECTOR.

In no wireless instrument have makeshift methods been more often resorted to than in the electrolytic detector. Designs for such detectors by men admittedly experts in the field display most amateurish crudity. The stumbling block has been, of course, the attachment for holding the delicate Wollaston wire. Amateurs become disgusted with fingering minute screws and discard a most excellent detector for a more convenient, if not so efficient, type.



The detector shown overcomes the difficulty in a novel way. *A* in the drawing is nothing more nor less than a tie-pin guard which may be obtained at any jewelry store, slipped through a suitable hole in a piece of spring brass and soldered thereto. By this method, putting in the Wollaston wire is made an easy matter and the principal objection to the electrolytic detector is removed.

LEWIS C. MUMFORD.

A FIXED CONDENSER.

Make a board three-quarters inch thick by 5¾ inches long by 3 inches wide.

Make another board three-quarters inch wide, by 5 inches high by 4¾ inches wide, nail or screw them together as shown in Figs. 1 and 2. Procure two test tubes seven-eighths inch by 6 inches, coat the inside and outside with tinfoil 4 inches wide. When this is done, procure two pieces of No. 14 copper wire about 6 or 7 inches long, solder to one

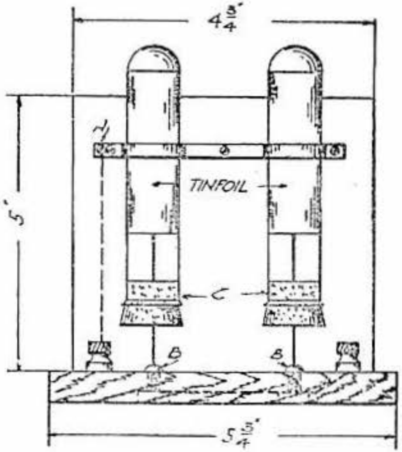

FIG. 1

end of each wire some fine copper wire taken from lamp cord. Then run them through corks that just fit the test tube, C, Fig. 1. The fine wires are to make contact with the inside foil, Fig. 4.

The tubes are held to the base by the battery binding posts, B, and the strip of brass, A. I think the drawing will explain any other questions.

TRANSFORMER FOR POULSEN TICKER.

Since a 15 k.w. Poulsen station will soon operate in Chicago the amateurs will want a ticker detector. Those not having A. C. cannot very well have one.

I have made one using an induction coil to get the A. C.

A core of iron wire ½ inch in diameter and six inches long is wound with two layers of No. 22 enameled copper wire. This is insulated and over this is wound two more layers of the same wire. This is the secondary, using a vibrator to interrupt the primary. When the primary circuit is closed the induced current flows in one direction and when the primary circuit is broken the induced current flows in the opposite direction. This gives an alternating current, the frequency depending on the speed of the vibrator. With 2 or 3 dry cells this will give good results.

ALFRED HOLMSTROM.

A SENSITIVE GALVANOMETER.

Here is a galvanometer which is very simple in construction and if properly made is only surpassed by the high resistance phone.

The base board may be of any good piece of wood of about 3x3 inches with holes drilled for binding posts. Now make a reel of cardboard or wood (the dimensions are clearly given in Fig. 1), and drill a hole for a brass tube at the top. Wind about one-fourth pound of No. 30 D.C.C. wire on the reel. Be sure that the same amount of wire is wound on either side of tube.

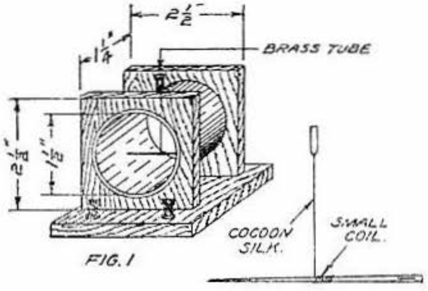

FIG. 1

FIG. 2

Now magnetize the finest needle you can find. Take a small piece of the wire and wrap three or four turns around the needle as shown at A in Fig. 2. Now place two or three inches of black silk thread on a sheet of writing paper. With one or two needles unravel one end of the thread until you have obtained a silk fibre that is scarcely visible to the naked eye. Put a drop of glue on the coil at A, Fig. 2, and carefully fasten the silk fibre to it. After the glue has thoroughly set balance the needle by pushing the coil toward or away from the eye. All the superfluous silk may be rolled upon the upper part of the thread.

Place the needle inside the coil; bring the end of the silk thread up through the brass tube and carefully pull the needle up till it is exactly in the center of the coil and fasten the thread with glue, to a wooden plug in the top of the tube. Next securely glue the coil to baseboard and connect to the binding posts. To exclude disturbing air currents, enclose with a glass case such as a lamp chimney. If the experimenter desires to compare currents with this galvanometer, place a graduated scale, drawn upon a piece of cardboard, just below the needle. Of course the coil must in any case be parallel with the magnetic meridian.

This instrument could be wonderfully improved by fastening a very small mirror to the needle and by causing a beam of light from a lamp to fall on the mirror, the reflected light could be focused on a scale placed on a suitable frame just in front of the lamp.

The author finds this apparatus so sensitive, that the tiny current generated by dipping a steel needle and piece of zinc (connected by wires to galvanometer) into a drop of salt water will set the needle swinging. Of course this instrument may be greatly improved in appearance, but the writer will leave that to the constructor.

ERNEST BARNHARD.

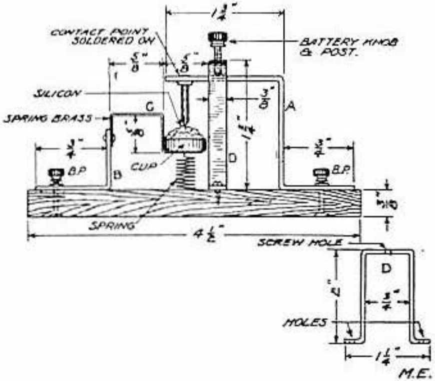
A SILICON DETECTOR

Here is a silicon detector which I am using in connection with my wireless set

The parts are mounted on a hard wood base 4½x1¼ inches and ⅜ inch thick.

Two pieces of brass, B, and D, are bent as shown in sketch. A, and C, are made of spring brass. All these are ⅜ inch wide, and of any convenient thickness. A small brass spring is placed under the end of C, supporting the cup.

The contact point, made of a small brass nail with the head flattened is soldered to A, as shown. All holes for screws are No. 19 drill and all tapped holes are made with a No. 29 drill and tapped 8-32 thread.



The sketch gives all necessary dimensions and shows how the detector is assembled.

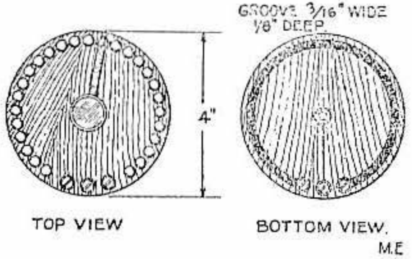
C. W. SEAMAN.

A CIRCULAR POTENTIOMETER.

The potentiometer here described is one which will, and does, give excellent results, and may be made by any one familiar with the use of tools in an hour's time at the cost of a few cents.

The dimensions are of small account, but the ones shown will be found to be very convenient. The base is turned from any hard wood, or hard rubber, if preferred, ½-inch thick and four inches in diameter. A groove is then turned in one side 3-16 inch wide by ⅛-inch deep and with a center diameter of 3½ inches. The holes are drilled nearly all around the groove 5-16 inch apart and large enough to admit 8-32 brass screws rather tightly. Then file the heads flat on enough screws to fill the holes and screw them in place. These screw heads should all be the same height, and the shanks should be a little less than ½-inch long. In the two holes at the end of the circle place two binding posts.

The groove is then filled with a paste made of lamp black and shellac. This will dry in a few days; and the resistance is about 500 ohms. If this is not enough it may be increased by adding a little powdered slate to the paste. Another excellent substance to use is the graphite which may be purchased for greasing bicycle chains. This may be melted and poured into the groove.



A switch lever is then attached and connection made with the middle binding post. The other two being placed at the ends of the groove, make connections with the paste when it is applied.

The chief advantage of this potentiometer is that it overcomes the trouble caused by imperfect contact when a graphite rod is used with a sliding contact.

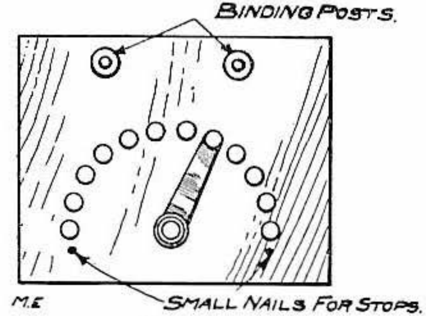
SIDNEY E. ANDERSON.

A COMPACT LOADING COIL.

Finding that the usual type of loading coil, such as described by Mr. Allen Dahlquist in the February issue of *Modern Electrics,* occupied too much space I devised a more compact one. Here it is:

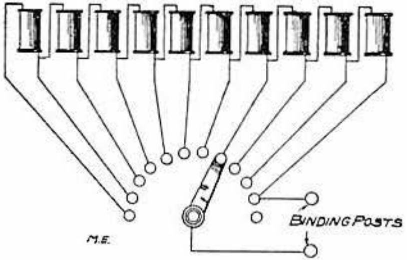


-FIG.1-

Make a box of some hard wood, preferably oak, having inside dimensions of 7x6x2½ inches.

On top of this mount a twelve point switch and two hard rubber binding posts at points indicated in Fig. I.

Next, from some ½ inch material cut ten pieces 2¼x6½ inches. Wind on each of these sixty feet of No. 24 enameled wire and place them in the box standing them side by side with a little space between each of them. A good way to insure against having them touch each other would be to slip a piece of cardboard between each one.



-FIG. 2-

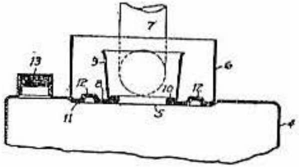


Figure II shows how the connections are made.

When all wiring is completed fill the box, containing the sections, with an insulating compound.

Screw the cover on with round headed brass screws.

If this coil is carefully made it will make an attractive addition to any amateur's set.

Contributed by HARRY HAAS.

THE CONSTRUCTION OF A ROTARY VARIABLE CONDENSER.

The following is a description of a rotary variable condenser that can be easily constructed by anyone without the use of many tools, and makes an efficient addition to any wireless station.

The accompanying diagrams give the necessary dimensions of the various parts. This condenser is built of a rather large number of small metal plates. This is done in order that it will not take up much room on the wireless table and still have a high capacity.

The condenser is chiefly used in connection with a loosely coupled tuning coil, as it's capacity is just about right for this.

Figure 1 shows a plan and elevation of the complete instrument. The top, shown in Fig. 2, is of hard rubber ¼-inch thick and 6 inches in diameter. Six holes are bored through it as shown. F is ¼-inch out of center and is ¼-inch in diameter. The three holes A, B, and C, are 90 degrees apart and ⅛-inch from the edge. The two holes, D and E, are for binding posts. All the holes except F are 3-16 inch in diameter.

The stationary plates, Fig. 3, are made of sheet brass 1-32 inch thick and are cut out to the shape of a semi-circle 6 inches in diameter. They have 3 holes bored in them to correspond with the holes A, B and C, in the top. Twelve of these plates will be needed.

The rotating plates are shown in Fig. 4. These are cut from 1-32 inch sheet brass, and have a radius of 2½ inches. A projecting lug, J, is left on and has a 3-16 inch hole in it. This hole must be ¼-inch from the straight edge of the plate. Eleven of these are needed.

Fig. 5 shows the bolts and separators. The bolt, K, 8-32 thread, is of brass, has a round head and is 3¾ inches long. Three will be needed. L, is a piece of brass tube that will slip over K and has an inside diameter 3-16 inch and an outside diameter of ¼-inch and is ⅜-inch long. Six of these will be needed. M, is a separator, which is 3-32 inch thick and ¼-inch outside diameter. It must

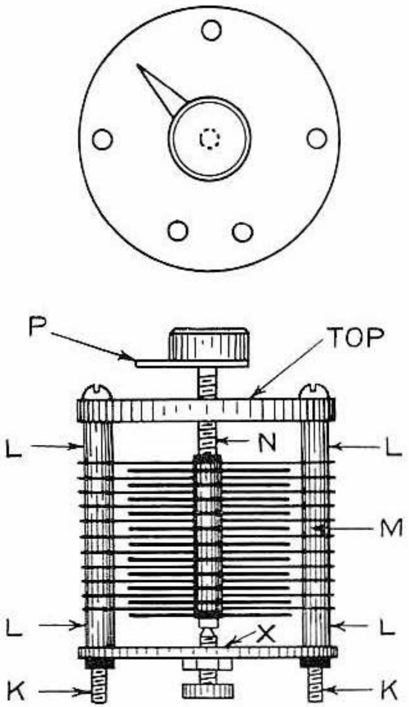

FIG. I

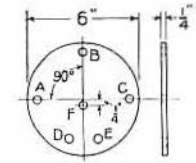
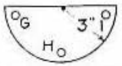


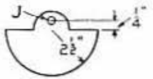
DETAILS OF TOP
FIG. 2



STATIONARY PLATE
FIG. 3 M.E.

be able to just make a firm fit on K Forty-three of these will be needed.

Fig. 6 shows the rotating pieces. N, is a piece of 8-32 threaded brass rod, 4 inches long and fitted with a hard rubber knob. The lower end of the rod should be hollowed out so as to fit over the point on the adjusting screw. O, is a piece of brass tube that is similar to L, in Fig. 5. P, is the pointer and is 2½ inches long, but its shape can be altered to suit the builder.



ROTATING PLATE
FIG. 4

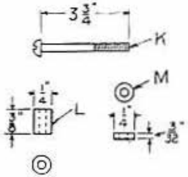


FIG. 5 M.E.

Fig. 7 shows the adjusting screw. It has a sharp point on the end and is threaded with an 8-32 thread. It is 1 inch long and has a locknut. The piece of hard rubber, X, is similar to the stationary plate; but has a lug, similar to that on the rotating plates. A hole is drilled and tapped in the lug with 8-32 thread.

threaded with an 8-32 thread. It is 1

The assembling is done as follows. First take the stationary part. Force the piece, O, in the hole, F, of the top. Then place the three bolts, K, in the holes, A, B, and C, of the top. Slip a piece, L, on each bolt, then a stationary plate, then a separator, one on each bolt, then another plate, separators, etc. After all the plates are on, put on the three remaining pieces, L, then the hard rubber plate, X, and fasten all tight with nuts on the ends of each bolt, K.

To assemble the rotating parts, first take the rod, N, and screw a nut to within ½-inch of the upper end. Put on a plate, separator, another plate, etc., until all the plates are on. Then fasten all firm with a locknut. Put the end of N up through the hole, F, of the top, and turn the plates so that they interlock. Put the adjusting screw in place and fit it into the hollow end of N. Adjust the screw until the plates swing clear. Connect the bushing, O, to one binding post and the bolt, K, to the other post. Put on the pointer and hard rubber knob.

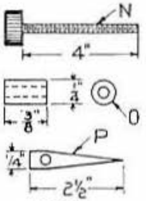

FIG. 6

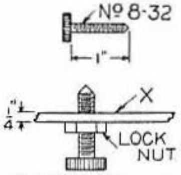

ADJUSTMENT SCREW.
FIG. 7 M.E.

The top may be marked off in 180 degrees. At 0, the capacity will be nil, and at 180 will be the maximum.

The condenser can be mounted in a case with the top exposed, or left open, as desired.

B. F. DASHIELL.

CAT WHISKER DETECTOR.

I enclose diagram of a wireless detector which I wish to enter in your prize contest. It is easily made and will give good service. Almost any kind of mineral may be used. Following are dimensions and directions for making:

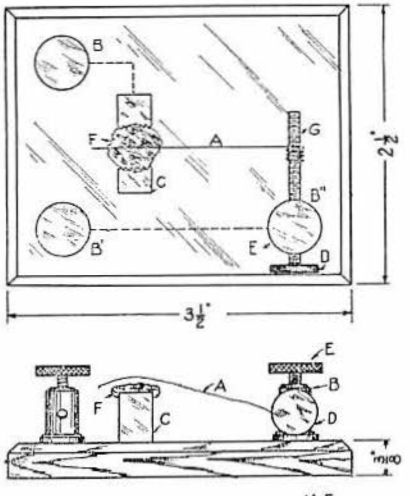
Base is of hard wood, three and one-half inches by two and one-half inches by three-eighths inch.

First procure three large binding

posts. In one of these tap a hole for the screw, G.

In a piece of brass, three-eighths inch wide and about two inches long, drill a hole in center for fastening to base, bend to shape shown, and file the edges like a saw, to hold crystal. Fasten binding posts and brass clip in positions as shown.

Thread a brass rod about one inch long, so as to fit the hole previously tapped. To one end of this, fasten a small rubber knob. Screw the rod into the binding post. To the other end of the rod solder a fine silver, or silver-plated, wire, so as to be in line with center of crystal holder. Connect one post to the clip and the other to the wire holder.



A, is the silver wire; B, B′, B″ are binding posts; C, is crystal holder; F, is crystal; E, is a lock screw on wire holder; D, is rubber knob; and G, the threaded rod.

Pressure of contact is adjusted by means of rubber knob and screw.

Contributed by

EARL ZANDER.

BALANCED DETECTOR STAND.

A is the base 5x2 inches; B is a double binding post, with top set screw removed; C is hole where lead wire goes in; D is hole in binding post for the balance rod, and the rod should fit easily in the hole, or the hole may be drilled to fit one-eighth inch rod; E is balance rod (one-eighth inch copper). The part, N, in Fig. 2 should be made first and put through the hole in B and then bent as shown. **F** is a counter weight and should be one-half inch in diameter and one-quarter inch thick with one-eighth inch hole in center to slip over balance rod E, and should have a small set screw, M. A small hole should be drilled in rod, E, at N, to receive the No. 30 steel or phosphor bronze wire, G, which should be bent as shown in Fig. 1, and be three-quarters inch from the end of balance rod to the point where it bends down to the mineral. Cup, H, should be not less than one-half inch in diameter, and should be soldered to plate, I, and drilled to receive small screw, J, and binding post, K, as in Fig. 1.

M. E. ARMSTRONG.

A WIRELESS OUTFIT FOR A DOLLAR.

Recently I finished constructing a wireless outfit, with which, while it cost me only one dollar to make, I am able to send and receive to the extent of over a quarter of a mile. My idea in building it was to see just how cheaply an outfit could be built.

The materials I bought are as follows, together with the prices:

1 Phone	$0.35
1 Buzzer	0.35
¼ Lb. No. 24 bare copper wire..	0.10
1/3 Lb. No. 14 bare aluminum wire	0.20
Total	$1.00

FIG. I

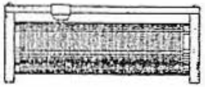

FIG. 2

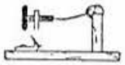

FIG. 3

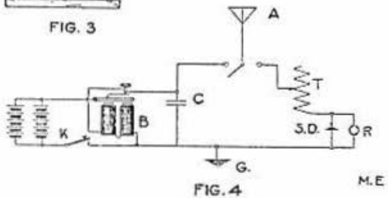

FIG. 4

The rest of the material I found lying around the house and was merely scrap.

The sending battery consists of (12) twelve dry cells connected in multiple-series (two rows of six cells in series). These batteries I got for nothing at different garages in the city, being considered no longer fit for use; but I found I could get quite a respectable current from them when a large number was used.

The key is made of strips of brass, (or other metals may be used) 1-32 inch by ½ inch. Figure 1 shows the key. The condenser is made of a 4 x 5 inch photograph plate with a sheet of tin foil 3 x 4 inches on each side and having a lug ½ inch wide extending out from the glass. Wrap the condenser with some thick brown paper and glue or bind it. The lugs should be wrapped around two (2) pieces of copper wire about six (6) inches long, and soldered or bound tightly with thread.

For the receiving set you will need a small tuner made as shown in Figure 2. The No. 24 bare copper wire is wound on with a thread between the turns. The design for the detector is shown in Figure 3. The contact on the silicon is made by a fine silver, gold or copper wire, but I find silver is the best.

The set is wired up on a baseboard as shown in Figure 4.

The aluminum wire was used in making the aerial.

Contributed by

LANCE BOYD.

A NEW TYPE OF VARIABLE CONDENSER.

Here is an easily made variable condenser.

It consists of a cylinder, A, fixed on a shaft, B, and arranged so that it can be made to rotate. A semi-cylindrical

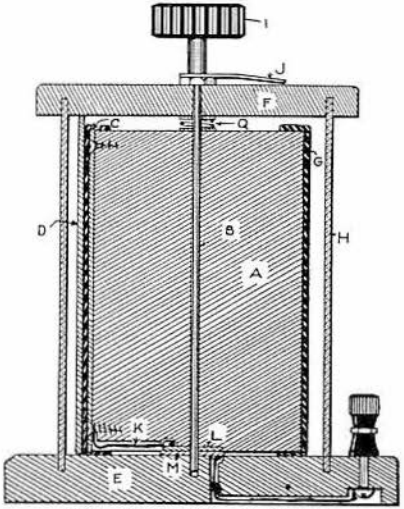

FIG. I. SECTIONAL ELEVATION

piece of sheet aluminum, C, is screwed to the cylinder, A, in a depression in the latter so that both surfaces lie flush. This is clearly shown in Fig. 2.

Over the cylinder, A, is glued a thin sheet of insulating material, G. In this instance it was paraffined paper but a coating of shellac, asphaltum, mica, etc., would be just as good. The seam, if it is made of paper or mica, is *not* over the metal plate.

Over this cylinder is made to bear another semi-cylindrical aluminum plate, D. This has four ears (two at the top and two at the bottom), projecting, and bent over four corresponding pieces of spring-brass wire. These wires are inserted in holes made in the base, E, and the cap, F, and are so bent that the plate, D, is made to bear upon the cylinder, A, with a light pressure.

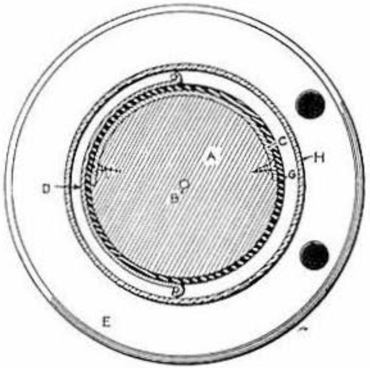

FIG. 2 CROSS SECTION

The base, E, and cap, F, are turned out of hardwood, to the shape shown, with grooves to admit the covering cylinder, H. This is made of aluminum, but it might as well be made of a sheet of black fibre, the seam being a lap joint. The reason a metal case was chosen was because it is more durable than fibre. It should have a tight fit in the grooves, as it is the only thing holding the base and cap together.

A large knob, I, is screwed on the shaft, B, and, beneath it, an aluminum index, J, is clamped with a hexagon nut.

The connections to the binding-posts are made as follows:

A wire, K, is caught under one of the screws holding the plate, C, to the cylinder, A. This wire is passed through a groove in the cylinder, as shown, to a washer, L, to which it is soldered. This washer makes contact with another washer, M, to which a wire is soldered. This wire is passed through a groove underneath the base to one of the binding posts. The other binding post is connected to one of the ears of the stationary plate, D, by a wire, running through another groove underneath the base.

Mention was made above of the cylinder, H, being of metal. The reader may have, at first thought, believed that this was not good, inasmuch as a short-circuit could accidentally be made. If the drawings are carefully observed, however, it will be seen that contact *might* be made between it and the plate, D, but a contact with the plate, C, is absolutely impossible.

A scale, H, for the index, J, to indicate the comparative capacity is made from a sheet of German silver and screwed to the cap, F. In my case the numbers and lines were etched upon it as follows:

It was covered with a thin coating of paraffin wax, and the characters scratched on it, so as to leave the surface of the German silver bare at those points. Then it was dipped in a bath of dilute nitric acid and left there for a while. When taken out it was washed in water and then dipped in boiling water to melt off the wax. The engraved surface was then painted over with asphaltum varnish, and when the latter had dried, it was washed off with a rag wet with gasoline. The varnish in the grooves made by the engraving remained, so that a neat and attractive, as well as durable, scale was the result. It will be noticed that German silver was used, instead of aluminum. This is because aluminum cannot be etched easily, as nitric acid has no effect upon it.

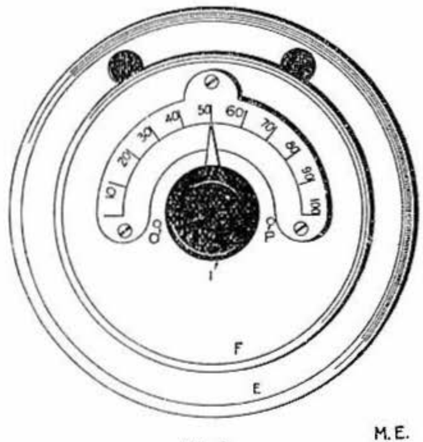

FIG. 3

Two pins, O and P, are inserted in the cap, F, at the points shown, to prevent the knob from being turned more than 180 degrees.

As the condenser may be operated at any angle, a small spring, Q, was inserted between two washers at the place shown, to keep the washers, L and M, in contact.

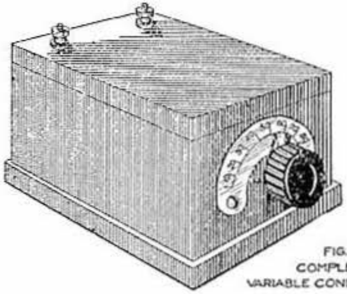

FIG. 4
COMPLETE
VARIABLE CONDENSER

From the description above, it would not seem that a condenser of this type could have a high capacity in a small space, as there are only about twenty-four square inches of active surface with a cylinder three and one-quarter inches in diameter and four and three-quarters inches long, the size which I adopted.

However, it must be borne in mind that the two plates, C and D, may be very close to each other, by making G very thin. In my case it is only 0.001 in. thick, resulting in a capacity of about 0.02 mfd.! The total space occupied by the condenser is seven and one-quarter inches by six inches by six inches.

The results were so gratifying that a smaller one was made, having a capacity of 0.005 mfd., and occupying a space of less than three and three-quarter inches by three inches by three inches (Fig. 4)! This also shows a different form of case.

Although not absolutely necessary, I found it to greatly increase the efficiency of the condenser if all the sharp edges of the plates, etc., were rounded with a file.

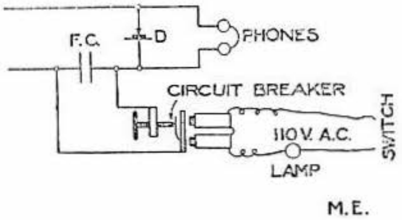
P. MERTZ.

SIMPLE POULSEN TICKER.

The present is a diagram of a Poulsen Ticker, which, I think, will be of interest to some amateurs. It is not necessary to have a telegraph relay, as shown in the February issue, in the Experimental Department. The fact that a relay was required



would prevent some from attempting to construct the ticker.

Instead of a relay I used a buzzer. Disconnect the magnets from the contact points and connect them as in the relay. Now connect to the contact points just as you would connect the relay contacts. You now have a ticker that is just as good as the one constructed from the relay, and it costs very much less.

Contributed by

JAS. LEROY HODGES.

A SEMIVARIABLE CONDENSER.

The following described variable condenser, which is built in sections, is very useful when one of the rotary, or plate type, cannot be obtained; or it may be used as an auxiliary. The condenser is of paraffined paper and tin foil, built in sections of whatever capacity is desired, and the method of construction is shown in sketch.

Procure a piece of one-quarter inch rod, seven inches long. Also a piece of five-sixteenths inch (outside) tubing, three inches long, to fit the rod. Tap the rod at both ends for an eight-thirty-two screw. Also procure two brass pillars, one-half inch high, five-eighths inch thick, with holes for an eight-thirty-two screw, an electrose knob, and some thin sheet brass.

Cut up the sheet brass into pieces and bore holes in them, as shown in Fig. 2. Cut as many as there are sections of the condenser. Then, assemble on the condenser case, or receiving cabinet, as shown in Fig. 1. Bend the brass contacts into the shape shown and fasten to the wood with small screws, connecting a section of the condenser to each one. Bend them up until each one nearly touches the one-quarter inch rod. Now, when the five-sixteenths inch tube slides over the rod it should touch all contacts. By pushing back and forth the number of sections, and hence the capacity, may be varied. The one-quarter inch rod is fastened to the board by eight-thirty-two screws from below, through the pillar, or by wood screws passing down from the top. A flat-headed eight-thirty-two screw is soldered to the tube and the electrose knob placed on it.

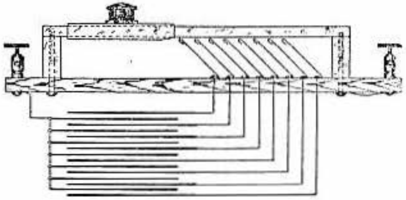


FIG. 1

FIG. 2 M.E.

If one side of each section be one sheet of tinfoil, having ten square inches of surface, and using paraffined linen paper, the capacity of each will be approximately .0001 mfd. If desired a pointer or hand from a clock may be fastened under the electrose knob, and a scale made, showing the capacity in circuit.

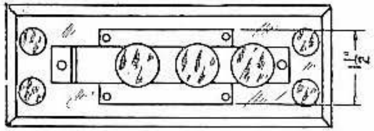
This condenser may be used wherever a variable condenser, or a fixed condenser of several capacities, is needed. It may be shunted across one of the rotary or slide plate type. Rough adjustment for capacity is made on this while finer adjustment is obtained by the plate type condenser. Sharp tuning is thus made possible.

Contributed by

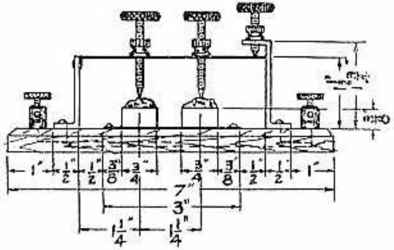
HENRY L. DAHM.

COMBINATION DETECTOR.

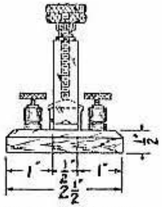
Enclosed please find a blue-print of a detector stand which I have worked out. This detector has a new idea as to the fine adjustment. Instead of having the fine adjustment screw between the contact and the standard, I have placed it on the other side of the contact, and therefore obtain a much finer adjustment. If you turn the screw down one-sixteenth of an inch the contact point will only go down one-thirty-second of an inch or less, where, as in the other kinds, the points would go down farther than the screw.



PLAN



SIDE VIEW



M. E. END VIEW

Another scheme is in the metal plate, on which the mineral cups rest. The plate is connected to a binding post, and the cups just rest on the plate. They can be moved around until the right part of the mineral is under the contact point.

I do not know whether you could use two minerals at the same time, but you can make a quick change from one to the other in this model. Some of the dimensions are not needed, but I think the drawing is clear.

ROBERT GIBSON.

INCREASED RECEIVING EFFICIENCY.

In most books dealing with wireless subjects, very little is said about three-slide tuners, so a word here would not be out of place.

Experimenters using single or double slide tuning coils will find that the selectivity of their station is increased from 25% to 50% by using a three-slide tuner in conjunction with a loop aerial, connecting instruments up as in Fig. 1. Excellent results can also be had from Fig. 2.

Any single or double slide coil can be converted into a triple slide coil at a cost of from twenty-five to fifty cents. After this has been done, get a piece of sheet copper, about 1-64th inch thick, and fasten it to the body of the coil, directly under one outside slider, so that when the slider is moved off the wire, it will slide onto the copper. Then connect this piece of copper to the other outside slider. Using the hookup shown in Fig. 2, if the slider is moved from the wire to the sheet copper, the loop aerial is converted to a straightaway aerial.

The writer believes that the method of connecting 'phones and detector (in series instead of in parallel), which was shown to him by a United Wireless operator, is new to most amateurs;

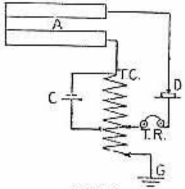

FIG. 1

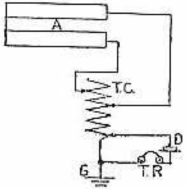

FIG. 2

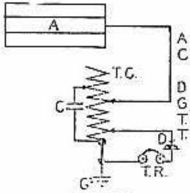

FIG. 3

A AERIAL
C CONDENSER (FIXED OR VARIABLE)
D CRYSTAL DETECTOR
G GROUND
T.C. TUNING COIL
T.R. TELEPHONE RECEIVERS.

M.E.

series instead of in parallel), which was shown to him by a United Wireless operator, is new to most amateurs; and, although it does not seem possible for the high frequency oscillations received by the aerial to go through the 'phones, whose inductance is very high, still such is the case.* Using crystal detectors, without a battery, such as perikon, galena, molybdenite, ferron, carborundum, etc., the signals come in fully 25% louder than when the 'phones are in parallel with the detector. When using a battery, the 'phones must necessarily be connected in parallel, but otherwise all connections are the same.

In case the experimenter has no loop aerial, and does not wish to convert his straightaway aerial into one of the loop type (which would amply repay him for the trouble and expense), the hook up shown in Fig. 3 gives very good results.

All of these "hook ups" were given several trials at a commercial station, as well as at the writer's station, and gave most gratifying results.

Contributed by
EDWARD B. WOOD.

**Note.*—The high frequency current does not pass through the 'phones, as stated. What does go through, in this case, is a rectified pulsating current. If the 'phones be shunted by a small fixed condenser, of about 0.002 mfd., still better results will be obtained. —Ed.

FASTENING COILS OF LOOSE COUPLERS.

The fastening of the primary and secondary coils to the wooden supports seems to trouble almost everyone who attempts to make a loose coupler. The following is a simple yet substantial method of overcoming this difficulty.

Cut out of a piece of one-half inch wood two circular pieces, one which will fit in the inside of the primary tube and the other in the inside of the secondary tube. This can be easily done with a knife or chisel. The primary can now be laid aside, as it is ready to fasten to the tube and also to the supports. The method of fastening is shown in Fig. 2.

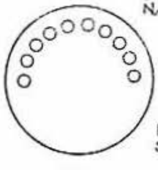

FIG. 1

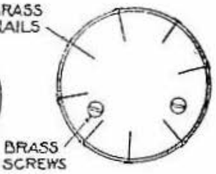

FIG. 2

M.E

Bore in the secondary as many holes as you are to have switch points on the secondary. If a slider is used on the secondary, it will not be necessary to bore any holes. Fig. 1 explains how the holes should be bored. They should be just wide enough for wire to pass through, as the wires from the various sections of the secondary pass through them to the switch points.

The switch points on the secondary support should be fastened so that the nuts will be below the surface of the wood, in order to allow the tube to be fastened on.

Brass nails and screws should be used as steel screws, or nails will become magnetized.

I have used this method with great success and found it to be much stronger than gluing the tubes in a groove.

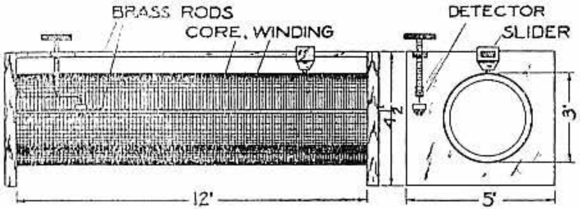
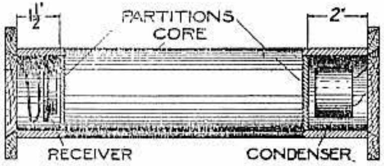
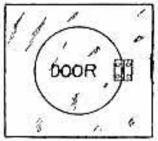
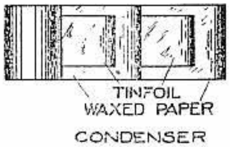
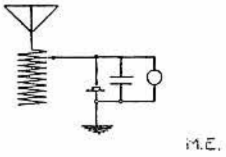
ELMER S. LINDMARK.











COMPACT PORTABLE RECEIVING SET.

The accompanying diagram shows a compact portable wireless receiving outfit.

The core of the tuning coil contains the condenser and is arranged to con- running from end to end of the coil serve as a support for the detector. The upper rod is tapped for the adjustment screw. The lower rod is tapped to receive a brass cup, containing the mineral. It is well to have several cups, each containing a different mineral. To change minerals, unscrew the cup and replace it with another.

The condenser is made by rolling long strips of waxed paper and tinfoil tightly around a wooden core. After it is rolled, tie it up and boil in paraffine. It is then placed in the tuning coil core and paraffine poured in around it.

A long piece of No. 18 annunciator wire will do for the aerial. It can be attached to a large box kite to raise it in the air. When not in use it can be wound on a wire spool.

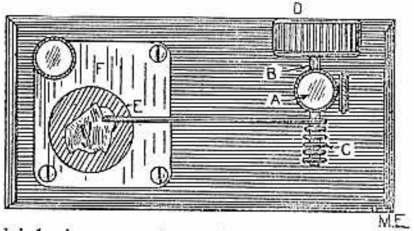
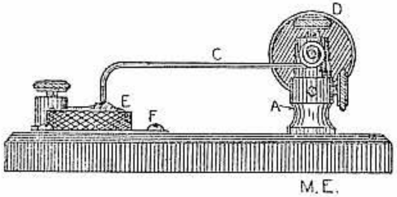
IMPROVED FORMS OF DETECTORS.

An improved form of detector, that is more convenient, and at the same time much simpler than the so-called "sensitive" detectors, which contain a mutiplicity of springs and hard-rubber knobs, and adjusting screws, is shown in the illustrations herewith.

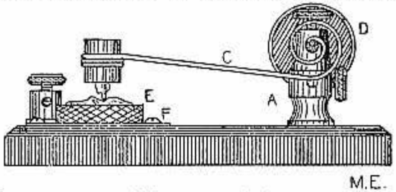
It consists of a double binding-post, A, through the upper connection of which is passed a shaft, B. On one side of this shaft is fastened a hard-rubber adjusting knob, D. On the other side is soldered a length of spring-brass wire, C, which is wound a few turns spirally, as shown in the drawing of the perikon detector; or



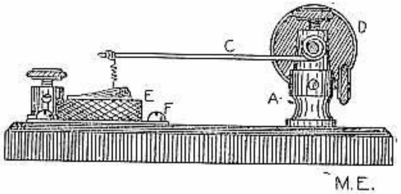


helically, as shown in that of the galena detector. The end of the wire is then brought out and bent as required.

For the silicon detector it is bluntly pointed at the end. For the galena, a small length of No. 30 copper wire is soldered, as shown. For the perikon detector, the end of the wire is wound around a piece of bornite, or chalcopyrite, mounted in metal, in the manner about to be described.



The lower mineral, E, is mounted in an alloy made of 3 parts solder to 1 part mercury. This is moulded into a "button," in a mold made by boring an inch hole through a piece of ¼ inch wood, and screwing this over another flat piece of wood. The crystals are set in while the metal is yet liquid, and, when it has thoroughly hardened, the edges of the metal button are knurled by rolling under a coarse file.



This button rests on a piece of sheet brass, or zinc, F, which is screwed to the base, and has a binding-post screwed over one corner.

The advantage of mounting the mineral this way, over mounting it in a cup, is clearly evident. Any part of the mineral can be reached quickly and conveniently, and a sensitive spot, when found, can be kept, because the point does not spring away.

The writer has found this type of detector far more convenient and sensitive than the so-called "sensitive" detectors, spoken of before, besides being much more easily and cheaply constructed.

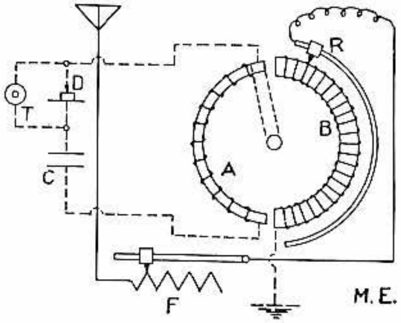
WIRELESS RECEIVING TUNER.

This is a very compact, loose coupled tuner, composed of two coils wound on hollow cores bent in the form of semicircles. The secondary coil is arranged to telescope into the primary, by turning a handle, which causes the secondary to swing round a central pivot. The primary is provided with a sliding contact, mounted on the curved rod, as shown. The diagram shows the tuner connected through a loading coil and with an ordinary detector circuit.



A NEW INDUCTIVE TUNER.

If carefully made, I believe the instrument here described will quickly prove its superiority over loose couplers of the sliding tube type, and, as an interference preventer, it is in a class by itself.

The wire is wound not unlike the ribbon of a pancake helix. Great care should be taken not to let the wire overlap. This may be accomplished by using a small amount of thick shellac which also adds to the insulation.

The drawings are practically self-explanatory, except for the taps. Taps should be taken out about every five feet on the primary, and every 30 feet on the secondary. Multiple point switches are placed on the backs of the coils, and the taps led to the switch points.

In Fig. 1, A and A¹, are blocks of wood 1 x 1 x 4 inches, screwed to the base, and which hold the ¼ inch brass rods, on which the secondary slides. The primary is screwed to A. B is a block 1 x 1 x 1 inch, screwed to the secondary, with a hole large enough to easily admit a ¼ inch rod drilled half way through it. B is a block 1 x 1 x 1 way through it. B is a block 1 x 1 x 1 inch, screwed to the secondary and has a ¼ inch hole drilled through it. C is a ¼ inch round brass rod 6½ inches long, upon which the secondary is mounted. D is a hardwood board 1 x 2 x 4 inches. E are four blocks 1 x 1 x 1½ inches, screwed to D, and have holes drilled through them to admit the ¼ inch rods, F. Binding posts, and the necessary switches, may be mounted on the base in the manner most convenient.

A COMPACT RECEIVING SET.

I designed this receiving set with the view of taking up as little room as possible. It can be screwed to the wall or to a window sill.

The wooden core of the tuning coil is 3½ inches in diameter and 9 inches long and is wound with No. 24 B. & S. enameled wire. The end blocks are 4x4½x½ inches and are screwed to the core. The slider rods are screwed on top of the ends.

The detector, Fig. 2, is mounted on one end of the tuner and on the other end is the condenser.

The detector is made of brass strip, battery screws, a battery cup, and other odds and ends as shown in Fig. 2.

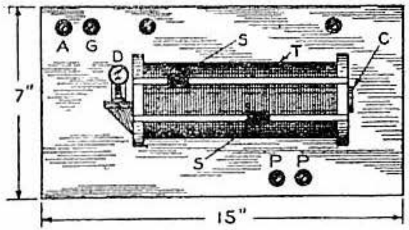

FIG. 1

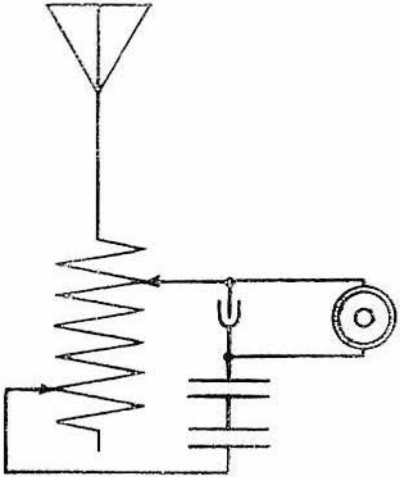

FIG. 3

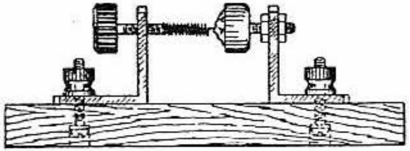

FIG. 2

The condenser is of the ordinary tinfoil and paper construction.

All the parts are fastened on the base, as in Fig. 1, which when screwed up lies flat against the wall.

The parts are connected as in Fig. 3.

A field mill for measuring atmospheric electricity

by Frank Thompson F.Thompson@manchester.ac.uk

Introduction

Every time we walk outside, we are bathed in force fields that are produced by nature. They are gravitational, magnetic and electric fields.

In the on-line text *Motion Mountain* – Volume 3, on page 209 – Christopher Schiller makes the following statement about electric fields:

"…every person should know that there is a vertical electric field of between 100 and 300 V/m on a clear day, as discovered in 1752; the earth is permanently negatively charged and, on a clear day, current flows downwards (electrons flow upwards) trying to discharge our planet."

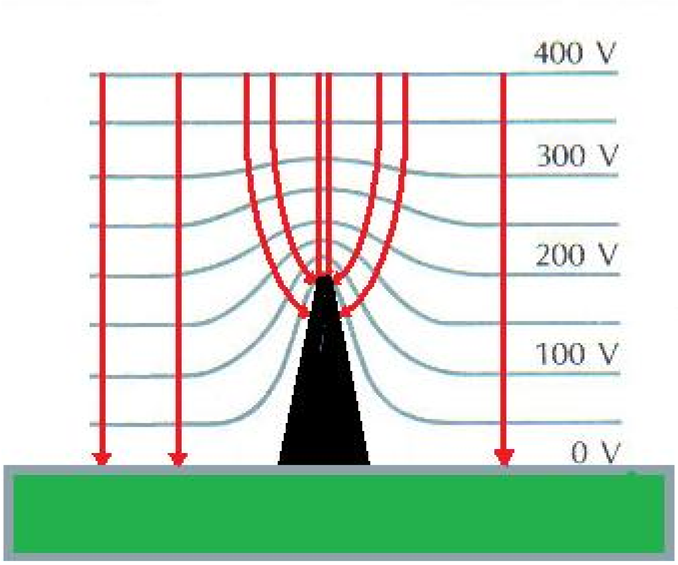

Figure 1 Distortion of field lines round a conducting object (grey - potential, red - field)

Now, we can all "feel" the gravitational force (just try jumping up and down) and we can easily detect magnetic fields with a compass needle. Indeed, these forces are very easily measured [1], [2]. The electric field, however, is more of a mystery and this is largely to do with the fact that it does not come indoors. This is a major obstacle to detection. An illustration is given in Figure 1:

Any conducting object at ground level will distort both potential and field lines of an electric field as shown. Houses, trees and people all have relatively good conductivity when compared to the surrounding air and therefore electric fields will not be present *inside* buildings at ground level.

It was taken as a challenge to measure this field and in doing so it was hoped that students would be made more aware of the vast topic of Atmospheric Physics.

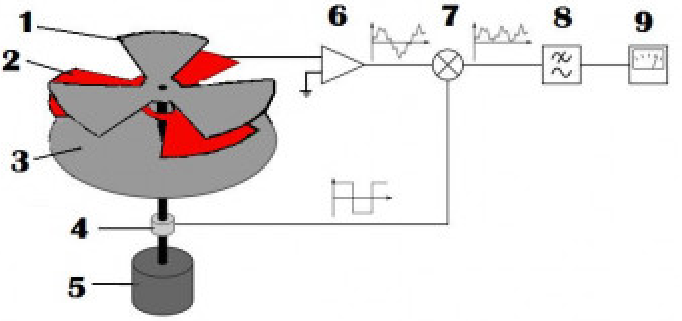
It may be worthwhile visiting "University of Reading METFiDAS weather observations". On this web page, note that PG (potential gradient) denotes electric field.

Graphical data, listed under the heading "Atmospheric Electricity" at the bottom of the web page, shows the electric field values for the particular location of Reading, UK.

Figure 2 - Diagram of a typical Field Mill with electronic circuitry

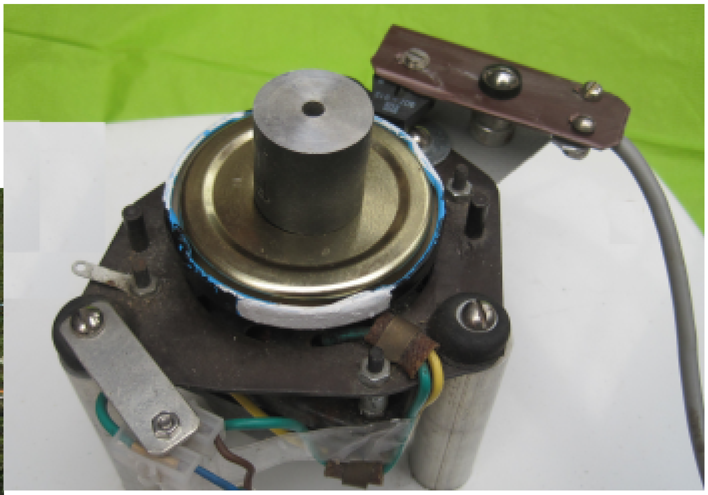
Apparatus

A little background reading showed that a Field Mill was the most common arrangement for this field measurement and a typical layout is shown in Figure 2:



The key for Figure 2 is as follows:
1 - **Rotor blade** at earth potential, turned by the **motor** (item **5**)
2 - **Fixed plate** isolated from earth (this is also called the **sensor plate**)
3 - **Ground plate**, also held at earth potential
4 - **Tachometer** with three equally spaced black and white partitions for its optical switch
5 - **Motor** providing power to the **rotor blade** (item **1**)
6 - **Charge amplifier**
7 - **Mixing device** and in the present apparatus it is a **multiplier circuit** AD 633
8 - **Low pass filter**
9 - **Centre-zero meter**

Figure 3 - Photograph showing the motor plus tachometer



In the present work, item **5** is a small motor with a disc attached to the spindle as shown in Figure 3:

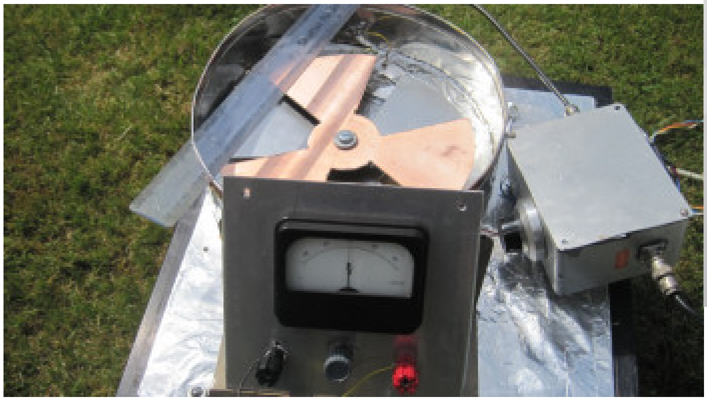


Figure 4 - Field Mill with separate charge amplifier (item 6) and centre-zero meter (item 9) resting on the case (ruler indicates the size of the apparatus)

Three black and three white stripes were painted on the rim so that the reflective optical-switch (RS Components Ltd, RS 307-913 or Optek OPB704W-Z supplied by Amazon) gave a square wave output signal.

The motor also turns the rotor blade (item **1**).

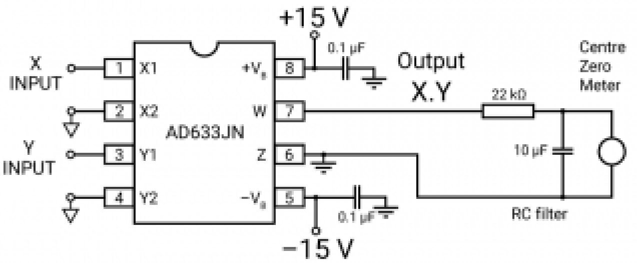
The ground plate (item **3)** is fabricated from a steel biscuit tin and the upper part of the spindle passes through.

The charge sensor plate (item **2**) is supported by this tin on insulated pillars and is alternately ***exposed to*** or ***shielded from*** the incident field by the rotor blade plate (item **1**).

The instrument/apparatus, positioned at gound level, is shown in Figure 4. Both the stationary and rotating blades are enclosed in a biscuit tin so allowing the instrument to be zeroed when the tin lid is placed on the tin. It also provided electrical shielding as extraneous noise from the motor was quite high.

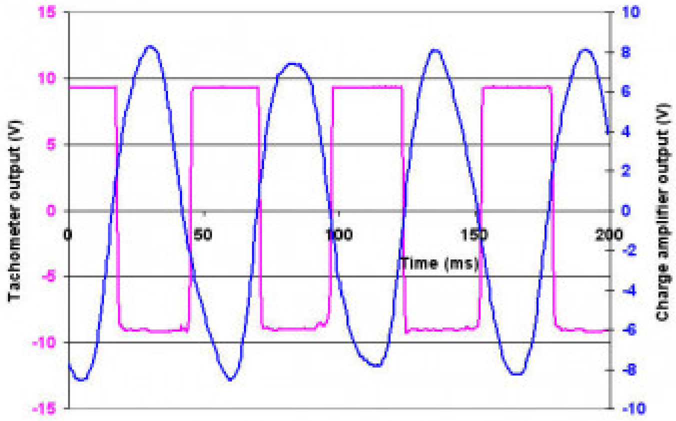
Figure 5 - Multiplier circuit (item 7) for mixing the tacho and charge signals (X and Y)

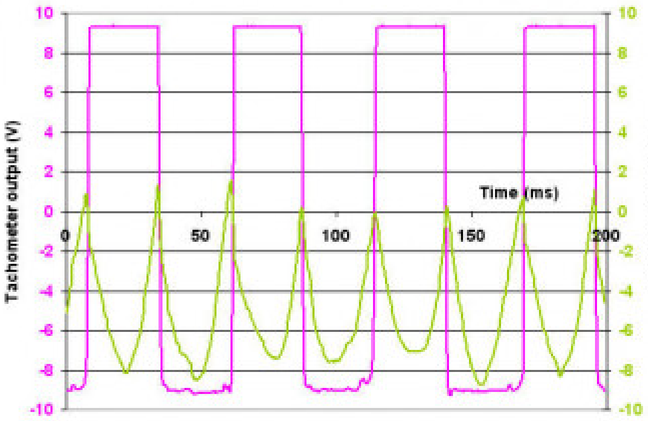
The charge amplifier, encased in a separate metallic box, rests on the case of the apparatus and is connected to the fixed plate (item **2**). If the signal from this amplifier were to be rectified then only the magnitude of the field would be measured and whether the field was incoming or outgoing would not be determined. But, by using ***a mixer*** (item **7**). we have synchronous demodulation which gives the sign of the field and a significant noise reduction. Commercial instruments are available for these measurements (e.g. Model 410 Scitech Instruments Ltd) and Figure 5 shows a low-cost alternative:



Basic multiplier connections

Figure 6 - Signals obtained when a charged PTFE rod is positioned over the Field Mill. (a) Signals from the tachometer (red) and the charge amplifier (blue)



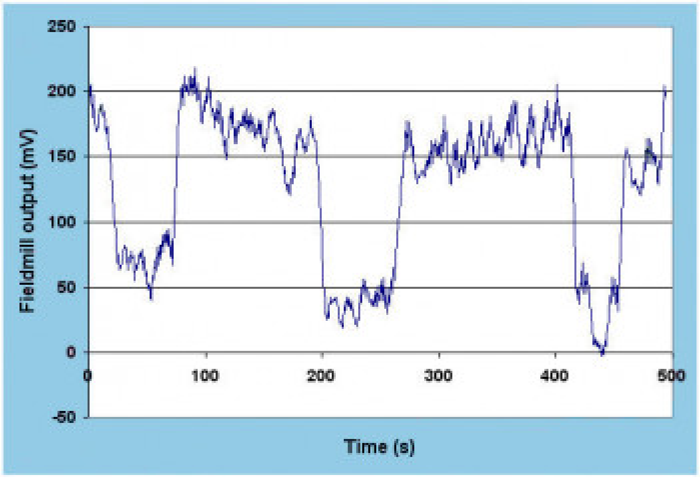


6(b) Signals from the tachometer (red) and the mixer (green)

In setting up the field mill one can place a charged object over the sensor plate (item 2) and observe the following signals. See Figure 6 (a), (b):

The output from the multiplier circuit is then passed through a low-pass filter and displayed on a centre-zero meter (item 9). The above readings (in Figure 6) were taken with a PicoScope 5242A oscilloscope and copied to Excel spreadsheets.

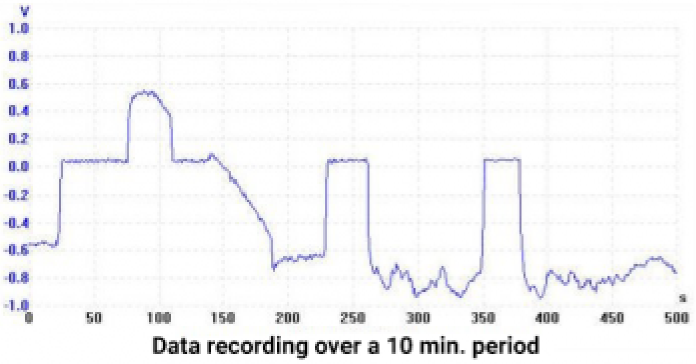
Preliminary results



After the setting up, we can be confident that the output voltage from the filtered signal is directly proportional to the earth’s field and a typical, fine day, outdoor graph is given in Figure 7:

As a very approximate calibration (carried out at the meteorological department of Reading University) the output readings in mV could be converted directly into field readings in V/m. Thus, the field mill gives the earth’s electric field as 120 (±20) Vm^-1 as the covered reading of approximately 50 mV is subtracted from the uncovered reading of 170 mV. Further measurements were made with the field mill on 22 June 2017. A thunderstorm had been forecast so there was a possibility of variability in the earth's electric field.

Figure 8 - Earth's electric field changes as a thunderstorm was approaching (rotor covered for periods 30–70, 107–140, 230–260 and 350–380 seconds).

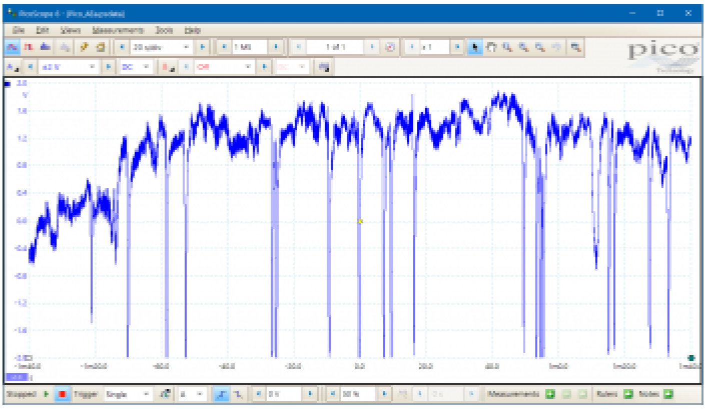


The apparatus was placed in an open space at about 8:15 am and the trace (Figure 8) was obtained. At approximately 8:30 am both the meter and the trace were off-scale, indicating a large negative signal. Adjustment of the gain by a factor of 10x restored an on-scale signal and, for several periods a zero signal condition was tested by placing the tin lid over the rotor. The changes in the signal were quite rapid as Figure 8 shows:

In Figure 8 we see that the earth's electric field changes from negative to positive in about 30 seconds and then the positive signal changes to negative in about 100 seconds.

The instrument had to be moved indoors after 600s as rainfall had commenced. Thunder and lightning occurred shortly afterwards. The electric field is seen to vary between +600 V/m and –1 kV/m.

Figure 9 - Trace showing the atmospheric electric field on a fine day



The PicoScope 5242A is ideal for data logging as the time scale can be set as long as 5000 seconds per division. Figure 9 shows a typical fine weather trace for about 5 mins:

For the initial minute the rotating blade was covered with the tin lid and then it was uncovered for the rest of the time. The observed spikes were assumed to be spurious but further measurements need to be carried out to see if they are caused by an instrumental defect.

Conclusions

On a fair-weather day, the Earth's electric field was found to be close to 120 V/m but the accuracy for these preliminary results was at best ±20%. This agrees with the Schiller statement. The offset error of approximately 50 mV is likely to result from imperfect blade dimensions and/or the black and white tachometer divisions as these were hand-painted.

The variability of the Earth's electric field (Reading University - graphical data showing potential gradient) does pose a problem so it is advisable to carry out measurements on a fine day and then the field will be close to 120 V/m.

As a final point, the signal-to-noise performance of the apparatus is very low even with blade diameters close to 20 cm. If one could replace the simple mixer with a phase sensitive detector (PSD) then improvements would be possible. The PSD would greatly simplify the setting up procedure of the apparatus as both gain and phase of the charge signal could then be adjusted.

(57) **ABSTRACT**

A permanent magnet device includes a permanent magnet having north and south pole faces with a first pole piece positioned adjacent one pole face thereof and a second pole piece positioned adjacent the other pole face thereof so as to create at least two potential magnetic flux paths. A first control coil is positioned along one flux path and a second control coil is positioned along the other flux path, each coil being connected to a control circuit for controlling the energization thereof. The control coils may be energized in a variety of ways to achieved desirable motive and static devices, including linear reciprocating devices, linear motion devices, rotary motion devices and power conversion.

METHODS FOR CONTROLLING THE PATH OF MAGNETIC FLUX FROM A PERMANENT MAGNET AND DEVICES INCORPORATING THE SAME

FIELD OF THE INVENTION

This invention relates generally to permanent magnet devices and more particularly, to a permanent magnet control component in which the flow of flux from a permanent magnet is controlled between two or more flux paths by utilizing timed delivery of electrical signals through one or more coils placed along at least one of the flux paths. Such permanent magnet control components may take on a variety of configurations facilitating use of such components in a variety of applications including applications involving the production of reciprocating, linear, and rotary motion and power conversion. Several novel permanent magnet rotary motion devices of motor constructions which operate by controlling the path of magnetic flux from one or more permanent magnets are described, such permanent magnet rotary motor constructions having increased efficiency and more desirable torque characteristics as compared to many currently used motors.

BACKGROUND OF THE INVENTION

Magnetic force of attraction is commonly used in a variety of types of permanent magnet devices including both linear and rotary motors. In the field of such permanent magnet devices there is a continuous pursuit of increased efficiency and reduced complexity.

Accordingly, an object of the present invention is to provide a permanent magnet control component in which the path of a given level of permanent magnet flux can be controlled by a lesser level of electromagnetic flux.

Another object of the present invention is to provide a permanent magnet control component in which substantially all of the flux from a permanent magnet can be switched between at least two different flux paths of the permanent magnet control component so as to enable useful work in the form of linear, reciprocating, and rotary motion.

Still another object of the present invention is to provide permanent magnet control components and motor constructions in which flux path control is provided by energizing an **1 0** electromagnet to oppose the magnetic flux of one or more permanent magnets.

Another object of the present invention is to provide permanent magnet control components and motor constructions in which flux path control is provided by energizing an electromagnet to aid the magnetic flux of one or more permanent magnets.

Yet another object of the present invention is to provide permanent magnet motor **15** constructions with improved operating characteristics.

SUMMARY OF THE INVENTION

These and other objects of the invention are attained by an apparatus which, in one aspect, is a permanent magnet device, comprising a permanent magnet having north and south pole faces, a first pole piece, a second pole piece, a first control coil, a second control coil, and circuit means, the first pole piece positioned adjacent the north pole face of the permanent magnet and including a first path portion, a second path portion and a third portion, the first path portion extending beyond a perimeter of the north pole face and the second path portion extending beyond the perimeter of the north pole face to define first and second flux paths for magnetic flux emanating from the north pole face of the permanent magnet, the first path portion of the first pole piece connected to the second path portion of the first pole piece by the third portion which extends across the north pole face of the permanent magnet, the second pole piece positioned adjacent the south pole face and including a first path portion and a second path portion, the first path portion extending beyond a perimeter of the south pole face and substantially aligned with the first path portion of the first pole piece, the second path portion extending beyond the perimeter of the south pole face and substantially aligned with the second path portion of the first pole piece, the first control coil positioned around the first path portion of the first pole piece, the second control coil positioned around the second path portion of the first pole piece, the circuit means connected to each of the first control coil and the second control coil to alternatingly energize the first coil and the second coil in a timed sequential manner.

Another aspect of the present invention provides a method for controlling the path of magnetic flux from a permanent magnet which involves placing a first pole piece adjacent a first pole face of the permanent magnet so as to have at least first and second path portions extending beyond a perimeter of the first pole face. A second pole piece is placed adjacent a second pole face of the permanent magnet so as to include at least one portion which substantially aligns with the first and second path portions of the first pole piece. A first control coil is placed along and around the first path portion of the first pole piece and a second control coil is placed along and around the second path portion of the first pole piece. The first control coil is repeatedly energized in a permanent magnet magnetic flux opposing manner so as to prevent magnetic flux of the permanent magnet from traversing the first path portion of the first pole piece, and the second control coil is repeatedly energized in a permanent magnet magnetic flux opposing manner so as to prevent magnetic flux of the permanent magnet from traversing the second path portion of the first pole piece.

Yet another aspect of the present invention provides a method for controlling the path of magnetic flux from a permanent magnet by placing a first pole piece adjacent a first pole face of the permanent magnet so as to have at least first and second path portions extending beyond a perimeter of the first pole face. A second pole piece is placed adjacent a second pole face of the permanent magnet so as to include at least one portion which substantially aligns with the first and second path portions of the first pole piece. A first control coil is placed along and around the first path portion of the first pole piece, and a second control coil is placed along and around the second path portion of the first pole piece. The following steps are alternatingly performed in a repeated manner:

(i) energizing the first control coil in a permanent magnet magnetic flux aiding manner so as to couple with substantially all magnetic flux of the permanent magnet such that substantially no magnetic flux of the permanent magnet traverses the second path portion of the first pole piece when the first control coil is so energized; and

(ii) energizing the second control coil in a permanent magnet magnetic flux opposing manner so as to couple with substantially all magnetic flux of the permanent magnet such that substantially no magnetic flux of the permanent magnet traverses the first path portion of the first pole piece when the second control coil is so energized.

A further aspect of the present invention provides method for controlling the path of magnetic flux from a permanent magnet by placing a first pole piece adjacent a first pole face of the permanent magnet so as to have at least first and second path portions extending beyond a perimeter of the first pole face, and placing a second pole piece adjacent a second pole face of the permanent magnet so as to include at least one portion which substantially aligns with the first and second path portions of the first pole piece. A first control coil is placed along and around the first path portion of the first pole piece, and a second control coil is placed along and around the second path portion of the first pole piece. The following steps are alternatingly performed in a repeated manner:

(i) energizing the first control coil in a permanent magnet magnetic flux aiding manner so as to couple with substantially all magnetic flux of the permanent magnet such that substantially no magnetic flux of the permanent magnet traverses the second path portion of the first pole piece when the first control coil is so energized; and

(ii) energizing the second control coil in a permanent magnet magnetic flux opposing manner so as to couple with substantially all magnetic flux of the permanent magnet such that substantially no magnetic flux of the permanent magnet traverses the first path portion of the first pole piece when the second control coil is so energized.

BRIEF DESCRIPTION OF THE INVENTION

For a better understanding of the present invention reference may be made to the accompanying drawings in which:

FIG. **1** is a perspective view of a magnetic device in which the magnetic flux from a magnetic member traverse a single path to produce a coupling force;

FIG. **2** is a perspective view of a magnetic device in which the magnetic flux from a magnetic member splits between two paths;

FIG. **3** is a side view of two magnetic members arrange in parallel between pole pieces;

FIG. **4** is a side view of two magnetic members arranged in series between pole pieces;

FIGS. **5**–**6** are side views of a permanent magnet device including a permanent magnet having pole pieces positioned against the pole faces thereof and including a movable armature;

FIGS. **7**–**9** are side views of a permanent magnet device including a permanent magnet having pole pieces positioned against the pole faces thereof to provide two magnetic flux paths and including a movable armature positionable along each magnetic flux path;

FIGS. **10**, **10**A–**10**H are perspective views of various embodiments of permanent magnet **5** control components which include two or more magnetic flux paths;

FIGS. **11**, **11**A–**11**F are side views of a permanent magnet device including a permanent magnet having pole pieces positioned against the pole faces thereof and including a movable armature and a permanent bypass extending between the pole pieces;

FIGS. **12**, **12**A–**12**E are side views of a two path permanent magnet device including two bypasses;

FIGS. **13**A–**13**C are side views of a permanent magnet linear reciprocating device;

FIG. **14** is a side view of an electromagnetic linear reciprocating device;

FIG. **15** is a side view of a two path permanent magnet device showing control coils energized in an exceeding manner;

FIGS. **16**A–E are a side view of a linear reciprocating device with control coils energized in an exceeding manner;

FIGS. **17**A–**17**D depict another embodiment of a linear reciprocating device;

FIGS. **18**A–**18**E show a linear motion device;

FIG. **19** is an exploded perspective view of a rotary motion device;

FIG. **20** is a partial assembled and cut away view of the rotary motion device of FIG. **19**;

FIGS. **21**A–**21**E are top views of the partial assembly of FIG. **20**, which views depict rotational motion thereof,

FIG. **22** is an assembled, cut-away view of the rotary motion device of FIG. **19** including a housing;

FIG. **23** is an exploded perspective view of another embodiment of a rotary motion device;

FIG. **24** is a perspective view of the rotary motion device of FIG. **23** as assembled;

FIGS. **25**A–**25**B are end views of the rotary motion device of FIG. **24** with the end cap removed to expose the rotor member;

FIGS. **26**–**28** show end views of various configurations for skewing the direction of rotation in the rotary motion device of FIG. **24**;

FIGS. **29**A–**29**D are end views of the rotary motion device of FIG. **24** illustrating a sequence of rotational movement thereof;

FIG. **30** is an exploded partial perspective view of another embodiment of a rotary motion device;

FIG. **31** is a perspective view of the rotary motion device of FIG. **30** as assembled

FIGS. **32**A–**32**D are top views of the rotary motion device of FIG. **31** illustrating rotational movement thereof;

FIG. **33** is a side view of the rotary motion device of FIG. **31** as assembled and including a housing;

FIG. **34** is a perspective view of another embodiment of a rotary motion device;

FIG. **35** is a top view of the rotary motion device of FIG. **34**;

FIG. **36** is a perspective view of the permanent magnet rotor member of the rotary motion device of FIG. **34**;

FIGS. **37** and **38** show alternative configurations for the control component incorporated into the rotary motion device of FIG. **34**;

FIGS. **39**A–**39**D are top views of the rotary motion device of FIG. **34** and depict rotational movement thereof;

FIGS. **40**–**44** are alternative variations of circuit means for controlling the timed energization of control coils in the various devices of the present invention;

FIGS. **45**A–**45**C and **45**X–**45**Z are side views of two path power conversion devices;

FIG. **46** is a schematic view of the permanent magnet portion of a rotor for use in some embodiments of the present device;

FIGS. **47** and **48** show other embodiments of a linear motion device;

FIG. **49** is a top view of another embodiment of a rotating motor like construction; and

FIG. **50** is a schematic view of one of the three stator portions of the device shown in FIG. **49**.

DETAILED DESCRIPTION OF THE DRAWINGS

Referring now to the drawings, FIGS. **1**–**4** are provided to facilitate an understanding of various aspects or features of the technology utilized in the present invention. FIG. **1** depicts a device **10** having a magnetic flux producing member **12** which may be a permanent magnet or electromagnet with magnetic poles **14** and **16** as shown. Pole pieces **18** and **20** are positioned adjacent respective poles **14** and **16** to provide a path for the magnetic flux of member **12**. Each pole piece **18** and **20** includes a respective pole piece end face **22** and **24**. As used throughout this specification it is understood that a pole piece, regardless of its shape or size, is preferably formed of soft iron, steel or some other magnetic material, with the preferred material being one which provides low reluctance, exhibits low hysterisis, and has a high magnetic flux density capability. Accordingly, the various pole pieces disclosed and described herein could likewise be of laminate type construction. Referring again to FIG. **1** an armature **26**, also formed of magnetic material, is shown with end faces **28** and **30** which are positioned and sized for being placed adjacent pole piece end faces **22** and **24**, such that when so positioned a substantially continuous low reluctance path **32** is provided for magnetic flux from north pole **14**, through pole piece **18**, through armature **26**, through pole piece **16**, and to south pole **16**. The magnetic flux traveling along such path **32** results in a force which tends to hold armature **26** in position adjacent pole piece end faces **22** and **24**. The resulting magnetic coupling or holding force F provided between adjacent pole piece end face **22** and armature end face **28**, and between adjacent pole piece end face **24** and armature end face **30**, can be approximated by the following equation:

$$F=B^2A/2\mu_0,$$

where B is the magnetic flux density passing through the adjacent end faces and where A is the surface area of the adjacent end faces. Assuming B uniform throughout flux path **32** and the area A of all end faces **22**, **24**, **28**, and **30** to be the same, the total holding force F_{T26} of armature **26** against pole pieces **18** and **20** will be:

$$F_{T26}=B^2A/\mu_0.$$

In FIG. **2** a device **40** having the same magnetic flux producing member **12** with magnetic poles **14** and **16** is shown. Pole pieces **42** and **44** are positioned adjacent respective pole faces **14** and **16** to provide two paths, as opposed to one above, for the magnetic flux of member **12**. In particular, pole piece **42** includes a first path portion **46** extending beyond a perimeter of north pole face **14** in one direction and a second path portion **48** extending beyond the perimeter of north pole face **14** in another direction. Similarly, pole piece **44** includes a first path portion **50** extending beyond the perimeter of south pole face **16** in one direction and a second path portion **52** extending beyond the perimeter of south pole face **16** in another direction. Each pole piece path portion **46**, **48**, **50**, **52** includes a respective end face. A first armature **54** is positionable adjacent the end faces of pole piece path portions **48** and **52** to provide a first magnetic flux path **56** and a second armature **58** is positionable adjacent the end faces of pole piece path portions **46** and **50** to provide a second magnetic flux path **60**. If the flux carrying area along flux paths **56** and **60** is the same as the flux carrying area along flux path **32** of FIG. **1**, the magnetic flux density along each flux path **56** and **60** will be one-half the magnetic flux density along flux path **32** of FIG. **1** because the same amount of flux is split between two like paths. The effect of dividing a given amount of magnetic flux along two like flux paths instead of along one flux path can be seen by examining the holding force on armature **54** as compared to the holding force on armature **26** of FIG. **1**. As already noted the magnetic flux density along path **56** will be one-half that along flux path **32** and thus the total holding force F_{T54} can be determined as:

$$F_{T54}=(B/2)2A/,\mu_0=B^2A/4\mu_0=F_{T26}/4.$$

It is therefore seen that dividing the same amount of magnetic flux along two flux paths rather than along one flux path reduces the magnetic holding or coupling force on an armature by one-fourth rather than one-half as might have been expected. This unexpected magnetic holding or coupling force differential, resulting from multiple flux paths, can provide advantageous properties in linear, reciprocating, and rotary motion devices.

Referring now to FIGS. **3**–**4**, the behavior of multiple magnetic flux sources arranged in parallel and series is described as compared to a single flux source. When identical flux sources or magnetic flux producing members **70** and **72** are positioned in parallel as shown in FIG. **3** with pole pieces **74** and **76** positioned adjacent the poles thereof to provide a flux path through armature **78**, the flux density B through armature **78** is double what the flux density would be if only one magnetic flux producing member were present. However, the field intensity H resulting from the two members **70** and **72** remains unchanged. This result holds true regardless of whether members **70** and **72** are both permanent magnets, are both electromagnets, or are a combination of one permanent magnet and one electromagnet. On the other hand, the properties resulting from magnetic flux producing members **80** and **82** arranged pole-to-pole in series between pole pieces **84** and **86**, with armature **88**, as shown in FIG. **4**, will vary depending on the nature of the members **80** and **82**.

In a first case, if both members **80** and **82** are permanent magnets, the magnetic field intensity H resulting from the two permanent magnets will be double that of one permanent magnet and the flux density B through armature **88** will be the same as what the flux density would be if only one permanent magnet type member were present.

In a second case, if both members **80** and **82** are electromagnets, the field intensity H again doubles and the flux density B increases according to the B/H curve or relationship of the pole piece **84**, **86** and armature **88** materials.

In a third case, if member **80** is a permanent magnet and member **82** is an electromagnet, the field intensity H again doubles, but, since the permanent magnet is near flux density saturation B_r the flux density can only be increased from B_r to B_{max} of the permanent magnet. At the point where electromagnet-type member **82** contacts permanent magnet-type member **80** the flux from the electromagnet-type member **82** couples with the flux of the permanent magnet-type member **82** until the flux density through permanent magnet-type member **80** reaches B_{max}. At that point additional flux from electromagnet-type member **82** does not contribute to the flux density along the flux path unless a bypass path around the permanent magnet-type member is provided. Use of such bypass paths will be described hereinbelow.

Controlling the flow of flux along both one and multiple flux paths is best described with reference to FIGS. **5**–**9**. In FIGS. **5** and **6** a permanent magnet device **90** including a permanent magnet **92** having pole pieces **94** and **96** positioned adjacent the pole faces thereof and an armature **98** completing a low reluctance path **104** from pole to pole is shown. Control coils **100, 102** are positioned along path **104**. When control coils **100, 102** are not energized, the magnetic flux of permanent magnet **92** follows path **104** as shown and armature **98** is held in place against pole pieces **94, 96** due to the resulting magnetic coupling forces. However, if coils **100, 102** are energized to provide an equal but opposing magnetic flux to that of permanent magnet **92**, the result is that the magnetic flux of permanent magnet **92** is blocked and no magnetic flux traverses the path which includes armature **98** and therefore no magnetic coupling forces act on armature **98** allowing it to fall away as shown in FIG. **6**. The permanent magnet device **90** is useful, although as will become apparent below, it is more advantageous to provide multiple flux paths rather than one.

In this regard, in FIG. **7** a permanent magnet device **110** includes a permanent magnet **112** having pole pieces **114, 116** positioned adjacent the pole faces thereof with armatures **118, 120** completing two low reluctance paths **130, 132** from pole to pole thereof. Control coils **122, 124** are positioned along path **130** and control coils **126, 128** are positioned along path **132**. The two paths provided are assumed to be of equal reluctance. With no coils energized, the magnetic flux of permanent magnet **112** divides equally along flux path **130** and along flux path **132** such that both armatures **118, 120** are subjected to a magnetic coupling force which holds them in place against pole pieces **114, 116**.

If coils **122, 124** are energized to provide a magnetic flux equal to but opposing the magnetic flux which travels along flux path **130** from permanent magnet **112** when no coils are energized, the result is that the magnetic flux of permanent magnet **112** is blocked and no magnetic flux traverses the path which includes armature **118** and therefore no magnetic coupling forces act on armature **118** allowing it to fall away as shown in FIG. **8**. Further, the magnetic flux traversing path **132** will be double that of when no coils are energized and therefore the magnetic coupling force on armature **120** will be about four (4) times that of when no coils are energized. By energizing coils **126, 128** in an opposing manner a similar result would be achieved such that armature **120** would fall away and such that the magnetic coupling force on armature **118** would be increased.

If coils **122, 124** are energized to provide a magnetic flux equal to and aiding the magnetic flux which travels along flux path **130** when no coils are energized, the result is that the control coils couple completely with the magnetic flux of permanent magnet **112** and no magnetic flux traverses the path which includes armature **120** and therefore no magnetic coupling forces act on armature **120** allowing it to fall away as shown in FIG. **9**. Further, the magnetic flux traversing path **130** will be double that of when no coils are energized and therefore the magnetic coupling force on armature **118** will be about four (4) times that when no coils are energized. By energizing coils **126, 128** in an aiding manner a similar result would be achieved such that armature **118** would fall away and the magnetic coupling force on armature **120** would be increased.

Based on the foregoing it is seen that the full magnetic coupling force available from the permanent magnet **112** can be switched from one path to another path by the application of one half the power it would require for a coil alone to produce the same magnetic flux along one path. The ability to easily switch the full magnetic coupling force from one path to another allows for efficient reciprocating, linear, and rotary motion and power conversion to be achieved.

The basic device utilized to achieve permanent magnet flux division and to control such permanent magnet flux division is defined herein as a "permanent magnet control component," various configurations of which are shown by way of example only, and not by way of limitation, in FIGS. **10**A–**10**F. FIG. **10**A depicts a permanent magnet control component **150** in which pole pieces **152** and **154** are positioned adjacent the pole faces of permanent magnet **156** to provide two magnetic flux paths extending from opposite sides of permanent magnet. Control coils **158** are positioned along each path. FIG. **10**B depicts a permanent magnet control component **160** in which pole pieces **162** and **164** are positioned against the pole faces of permanent magnet **166** to provide two spaced, adjacent magnetic flux paths extending from the same side of permanent magnet **166**. Control coils **168** are positioned along each path. FIG. **10**C depicts a permanent magnet control component **170** in which pole pieces **172** and **174** are configured so as to be positioned adjacent the pole faces of permanent magnet **176** so as to provide four flux paths, each flux path extending in a respective direction from permanent magnet **176**. Control coils **178** are also positioned along each path. FIG. **10**D depicts another four path configuration of a permanent magnet control component **180** in which pole pieces **182, 184** are configured and positioned to provide four flux paths for permanent magnet **186**, with a pair of spaced, adjacent flux paths extending from each side of permanent magnet **186**. Control coils **188** are positioned along each path. FIG. **10**E depicts another four path configuration of a permanent magnet control component **190** in which all four flux paths formed by pole pieces **192, 194** extend from one side of permanent magnet **196**. Again, control coils **198** are positioned along each flux path. FIG. **10**F still further depicts a four path configuration of a permanent magnet control component **200** in which pole pieces **202, 204** extend to one side of permanent magnet **206**, with pole piece **202** defining four flux paths and with pole piece **204** including a continuous return path. Control coils **208** are positioned along each path of pole piece **202**. Many other variations are possible.

Accordingly, it is seen that a variety of different configurations of permanent magnet control components in accordance with the present invention are possible. The important considerations for division of permanent magnet flux in such permanent magnet control components include extending each pole piece to or beyond the outer perimeter of the pole face of the permanent magnet in each region where a flux path is intended and assuring that the pole face of the permanent magnet intersects each of the flux paths. It is not necessary for each pole piece to include the same number of path portions extending beyond the perimeter of the respective permanent magnet pole face as noted with reference to permanent magnet control component **200**. Although two control coils are shown along each of the flux paths in FIGS. **10**A–**10**E it is apparent from component **200** in FIG. **10**F that one control coil positioned along a flux path is generally sufficient for purposes of the present invention. Further, although in the illustrated configurations each pole piece is positioned to contact a respective pole face of the permanent magnet, a small spacing between a pole piece and its adjacent permanent magnet pole face could be provided, particularly in applications where relative movement between the subject pole piece and the permanent magnet will occur.

In its simplest form a two path permanent magnet control component only requires one control coil positioned along one of the control paths to permit the magnetic flux of a permanent magnet to be switched between the two paths. In particular, a side view of such a two path component **210** is shown in FIG. **10**G and includes a permanent magnet **211** pole pieces **212** and **213**, and control coil **214** which may be connected to a suitable control circuit. By alternating energizing control coil **214** in an opposing manner and an aiding manner the magnetic flux of permanent magnet can be switched between the path including armature **215** and the path including armature **216**. When control coil **214** is energized in an opposing manner the magnetic flux will traverse the path including armature **215** and when control coil **214** is energized in an aiding manner the magnetic flux will traverse the path including armature **216**. Control coil **214** could also be placed at anyone of positions **217, 218**, or **219** to achieve the flux path switching. Further, in the two coils embodiment shown in FIG. **10**H control coil **217** is added. In such a device flux switching can be achieved by simultaneously energizing control coil **214** in a flux aiding manner and control coil **217** in a flux opposing manner, and by then simultaneously reversing the energization of the respective control coils **214** and **217**.

Reference is made to FIGS. **11**A–**11**F which depict devices similar to that of FIGS. **5**–**6** except that a bypass, formed of magnetic material, is provided in each case. In device **220** of FIGS. **11**A–**11**C a bypass **222** is provided from pole piece **224** to pole piece **226** and is located between permanent magnet **228** and control coils **230, 232**, with armature **234** located adjacent the ends of pole pieces **224, 226**. In FIG. **11**A with no coil energization, magnet flux components **236** and **237** travel as shown. When coils **230** and **232** are energized in an aiding or adding manner as in FIG. **11**B, the result is permanent magnet magnetic flux components **236** and **237** traveling as shown, and with the added magnetic flux component **238** from coils **230** and **232** also traveling as shown. Thus, in device **220** energizing the coils in an aiding manner results in an increased magnetic coupling force on armature **234**. In FIG. **11**C coils **230, 232** are energized in an opposing exceeding manner which results in permanent magnetic flux components **236** and **237** traveling as shown and excess magnetic flux component **238** traveling as shown. Thus, in device **220** energizing the coils in an opposing exceeding manner results in magnetic coupling force on armature **234**, albeit smaller than that in the aiding exceeding case.

In device **240** of FIGS. **11**D–**11**F a bypass **242** is provided between pole piece **244** and pole piece **246** but is located on an opposite side of permanent magnet **248** as compared to control coils **250, 252** and armature **254**. Permanent magnet flux components **256** and **257** are shown for no coil energization in FIG. **11**D. In FIG. **11**E the paths of permanent magnet flux components **256** and **257**, as well as excess coil magnetic flux **258**, are shown when coils **250, 252** are energized in an aiding exceeding manner. In FIG. **11**F the path of each magnetic flux component **256, 257**, and **258** is shown when coils **230, 232** are energized in an opposed exceeding manner.

FIGS. **12**A–**12**E depict a device **270** similar to that shown in FIGS. **7**–**9** except that bypasses **272** and **274** are provided from pole piece **276** to pole piece **278**. Bypass **272** is located between permanent magnet **280** and control coils **282, 284** and bypass **274** is located between permanent magnet **280** and control coils **286, 288**. Armatures **290** and **292** are also provided. When no coils are energized permanent magnet magnetic flux components **294, 296, 298**, and **300** travel as shown in FIG. **12**A.

If coils **282, 284** are energized in an opposing manner permanent magnet flux components **295, 297**, and **299** travel as shown, with no flux component traversing the path which includes armature **290** and therefore no magnetic coupling force acting thereon. This would be the case for when coils **282, 284** are energized to the level where the coils magnetic flux just blocks, but does not exceed, the magnetic flux component **294** (FIG. **12**A) from permanent magnet **280**. If, however, coils **282, 284** are energized in an opposed exceeding manner an excess coil magnetic flux component **301** is produced which travels a path including armature **290** and bypass **272** results as shown in FIG. **12**C.

Coils **286, 288** may be energized in an aiding manner such that all permanent magnet magnetic flux travels along the path which includes armature **292** as shown in FIG. **12**D. If coils **286, 288** are energized in excess of the level of FIG. **12**D then the excess magnetic flux component **304** traverses the path which includes armature **292** and bypass **274** as shown in FIG. **12**E, thereby increasing the magnetic coupling force on armature **292** as compared to FIG. **12**D. The advantage of incorporating such bypasses into permanent magnet control components in certain applications will become apparent below.

Reciprocating Motion

As mentioned above, controlling the path of magnetic flux from a permanent magnet can be useful in a variety of applications such as achieving reciprocating motion. In this regard, if the device **110** of FIGS. **7**–**9** is modified such that armatures **118** and **120** are fixed to a sliding shaft **320** as shown in FIGS. **13**A–**13**C, and if the distance between the armatures is greater than the end to end length of pole pieces **114, 116**, limited linear motion in two directions (left and right in FIGS. **13**A–**13**C), and therefore linear reciprocating motion, can be achieved by the timed, alternate delivery of electrical signals to control coils **122, 124** and control coils **126, 128**. By way of example, FIG. **13**A represents the position of shaft connected armatures **118, 120** when coils **122, 124** are energized in an opposing manner to block the flux of permanent magnet **112** such that all magnetic flux traverses path **132** as shown and such that the resulting magnetic coupling force acts to the left as indicated by arrow **322**. As shown in FIG. **13**B when coils **122, 124** are de-energized the magnetic flux from permanent magnet **112** can again travel along path **130** through armature **118**. However, due to the air gap **324** between armature **118** and pole pieces **114, 116** the reluctance along path **130** will be significantly greater than the reluctance along path **132**. Accordingly, the amount of magnetic flux which flows along path **130** will be less than the amount of magnetic flux which flows along path **132** such that the magnetic coupling force on armature **118** acting to the right will be significantly less than the magnetic coupling force on armature **120** acting to the left as shown by arrows **326** and **328**, which arrows are sized to represent the strength of the respective directional force. FIG. **13**C represents the position of shaft connected armatures **118, 120** after coils **126, 128** are energized in a manner to oppose the flux of permanent magnet **112** such that all flux traverses path **130** and the resulting magnetic coupling force on armature **118**, depicted by arrow **330**, moves the shaft **10** connected armatures **118, 120** to the right.

Control coils **122, 124** and **126, 128** could also be energized in a flux aiding manner to achieve the same result. In such a device, FIG. **13**A would represent coils **126, 128** energized to aid magnetic flux along path **132**, FIG. **13**B would again represent no coils energized, and FIG. **13**C would represent coils **122, 124** energized to aid magnetic flux along path **130**.

Thus, by alternatingly energizing and de-energizing control coils **122, 124** and **126, 128** a linear reciprocating motion of shaft connected armatures **118, 120** may be achieved. Further, such reciprocating motion may be achieved by energizing the coils in either an opposing or aiding manner. The magnetic coupling force exerted on a given armature when 20 the control coils are energized to establish all magnetic flux along a single path which includes that armature is significantly greater than the magnetic coupling force which would be exerted on such armature by an identical energization of the control coils in the absence of the permanent magnet. This is demonstrated with reference to FIG. **14** which depicts a reciprocating device **340** in which only coils or electromagnets are utilized. As shown armatures **342** and **344** are connected by shaft **346**, and each armature **342, 344** includes a respective U-shaped pole path piece **348, 350** which pole path pieces are mechanically connected by a non-magnetic material **352**. Each pole path piece **348** and **350** has respective control coils **354, 356** and **358, 360** positioned therealong. By comparison with the device of FIGS. **13**A–**13**C, if coils **358, 360** of device **340** are energized to cause magnetic flux flow in either direction, clockwise or counterclockwise, along path **362**, the amount of electrical energy which would be required in order to achieve the same magnetic coupling force on armature **344** as achieved on armature **120** above in FIG. **13**A would be twice that delivered to coils **122, 124** or **126, 128** in FIG. **13**A. It is therefore demonstrated that by controlling or switching the flow of magnetic flux from a permanent magnet between at least two different paths results in greater coupling forces per unit of input electrical energy, and therefore that such control or switching will enable more work to be achieved per unit of input electrical energy.

As described above, if a coil is energized beyond the point where the magnetic flux produced by the coil aiding the amount of the permanent magnet's flux that is either opposed or aided, the extra magnetic flux needs a low reluctance path between the poles of the coil that produces the excess magnetic flux. If a complete low reluctance path is not provided for the excess magnetic flux there is little potential for taking advantage of the excess magnetic flux in terms of producing additional magnetic coupling forces. The path for such excess flux cannot be through a permanent magnet member. In assemblies which include an armature on each path, the armature will provide the necessary low reluctance path. Referring to FIG. **15**, various components of the magnetic flux in device **110** (FIGS. **7**–**9**) are depicted by numerals **380, 382**, and **384** for the case when coils **122, 124** are energized to oppose the magnetic flux of permanent magnet **112** in an amount which exceeds the level of magnetic flux which permanent magnet **112** would cause to flow through armature **118** when no coils are energized. FIG. **15** is likewise representative of the case when coils **126, 128** are energized to aid the magnetic flux of permanent magnet **112** in an amount which exceeds the level of magnetic flux which permanent magnet **112** would cause to flow through armature **118** when no coils are energized. In particular, magnetic flux component **380** represents the magnetic flux of permanent magnet **112** which normally flows through the path including armature **120**; magnetic flux component **382** represents the magnetic flux of permanent magnet **112** which is diverted by the opposing field of coils **122, 124** so as to traverse the path which includes armature **120**; and magnetic flux component **384** represents the magnetic flux produced by coils **122, 124** which is in excess of the diverted magnetic flux **382**. As shown, the excess magnetic flux **384** produced by coils **122, 124** traverses the path which includes armature **120** and bypasses permanent magnet **112** so as to also traverse the path which includes armature **118**. Thus, the excess magnetic flux produced by coils **122, 124** adds to the permanent magnet flux traversing the path which includes armature **120**, thus increasing the magnetic coupling force on armature **120**, while at the same time providing a magnetic coupling force on armature **118**.

In a reciprocating device where armatures **118** and **120** are connected by shaft **320** as shown in FIGS. **13**A–**13**C and again in FIG. **16**, excess magnetic flux **384** will increase magnetic coupling force **390** on armature **120** acting to the left. However, because such excess flux **384** also traverses the path which includes armature **118**, such excess magnetic flux **384** also results in a magnetic coupling force **392** on armature **118** which acts to the right. Even though excess magnetic flux **384** traversing the path which includes an armature **118** has an opposite polarity to that which would traverse the path due to permanent magnet **112**, the magnetic coupling force on armature **118** still acts to the right because armature **118** is not polarity sensitive, that is, armature **118** will be attracted regardless of the direction of the magnetic flux traversing the path. The overall effect is that a resultant force which is the difference between force **390** and force **392** will act on the shaft-connected armatures **118, 120**. However, if armatures **118** and **120** were formed by permanent magnets having polarities as shown at the top and bottom of such armatures, the force acting on each armature would be in the same direction and therefore additive.

In this regard reference is made to FIG. **16**B in which a two path device **371** having four control coils **373, 375, 377** and **379** is shown with the illustrated armatures being formed by permanent magnets **381** and **383** having polarities as shown. With no coils energized both permanent magnet armatures **381** and **383** are attracted to the ends of pole pieces **385** and **387**. With coils **373 375** energized in an opposing manner and coils **377, 379** energized in an aiding manner, the attractive force on permanent magnet armature **383** will generally increase and the attractive force on permanent magnet armature **381** will generally decrease. This is demonstrated with reference to the graph of FIG. **16**C which depicts a graph of the current flowing in the control coils on the x-axis verses the magnetic flux in gauss on the y-axis with line **389** representing the flux along the aiding side of device **371** and line **391** representing the flux along the opposing side of device **371**. As shown the magnetic flux on the coil opposing side decreases as the coil current increases and passed through zero at point **393**. After point **393** reverse magnetic flux begins to be produced and would result in a repelling force on permanent magnet armature **381**. In some applications particularly those where permanent magnet armatures and rotors are not utilized, it will be critical to recognize point **393** so that reverse magnetic flux is not produced. In this regard reference is made to FIGS. **16**D and **16**E in which use of Hall Effect switches **401** and **403** is incorporated to enable controlling the coil energizing current in situations where it is desirable to prevent reverse magnetic flux. As shown small bypasses **405** and **407** are provided with Hall Effect switches **401** and **403** disposed in gaps therealong, the switches being connected to control circuit **409**. As the flux traveling along the bypass path falls to zero the Hall Effect switch can be utilized to prevent further energization of the control coils so that no reverse flux is created.

Another embodiment of a device **400** which would provide reciprocating motion is shown in FIGS. **17**A–**17**D in which a permanent magnet control component **402** having two flux paths may is provided. A first pole piece **404** has two spaced, adjacent path portions **406** and **408** extending beyond the perimeter of the pole face of permanent magnet

410, and a second pole piece **412** includes only one continuous portion **414** extending beyond the perimeter of the pole face of permanent magnet **410**, each path portion **406** and **408** of pole piece **404** being substantially aligned with at least a part of portion **414** of pole piece **412**. Control coil **416** is positioned along pole piece path portion **406** and control coil **418** is positioned along pole piece portion **408**. An armature **420** is positioned in the region between pole piece path portions **404**, **406** and pole piece portion **414** and is free to slide from side to side as shown by arrows **422** and **424**. A front view of component device **400** with no coils energized and armature **420** at a mid-point depicts flux flowing from the north pole face of permanent magnet **410**, through each of pole piece path portions **406** and **408**, through armature **420**, and returning to the south pole face through pole piece portion **414**. Thus, the magnetic flux divides equally along two paths. If coil **416** is energized in an aiding manner, or if coil **418** is energized in an opposing manner, all or a majority of the permanent magnets'magnetic flux can be made to flow through pole piece portion **406** such that a resulting magnetic coupling force on armature **420** causes it to move to the left as shown in FIG. **17**C.

Likewise, if control coil **416** is energized in an opposing manner, or if control coil **418** is energized in an aiding manner, all or a majority of the permanent magnet flux can be made to flow through pole piece path portion **408** such that a resulting magnetic coupling force on armature **420** causes it to move to the right as shown in FIG. **17**D. Accordingly, by alternately energizing and de-energizing coils **416** and **418** a reciprocating motion of armature **420** may be achieved.

Linear Motion

Referring now to FIGS. **18**A–**18**E, linear motion in accordance with the present invention is described. In particular, a permanent magnet control component **440** including a permanent magnet **442** with a pole piece **444** positioned against the north pole face thereof and a pole piece **446** positioned against the south pole face thereof is shown in an exploded view in FIG. **18**A and assembled in FIG. **18**B. Pole piece **444** includes five path portions **448**A–**448**E which extend beyond the perimeter of the north pole face of permanent magnet **442** to one side thereof and at respective positions along the length thereof, each path portion **448**A–**448**E including a respective control coil **450**A–**450**E positioned therearound. Pole piece **446** includes one portion **452** extending beyond the perimeter of the south pole face of permanent magnet **442** to the one side thereof, which portion **452** extends along the entire length of permanent magnet **442**. A plurality of armatures **454** define a path of relative movement between permanent magnet control component **440** and such armatures **454**, and by providing timed energization of given control coils **450**A–**450**E such relative movement can be achieved. The sequence of side views depicted in FIGS. **18**C–**18**E illustrate such relative movement, with coils **450**A, **450**C and **450**E being energized in an opposing manner simultaneously in FIG. **18**C, with coils **450**A and **450**D being energized simultaneously in an opposing manner in FIG. **18**D, and with coils **450**B and **450**D being energized simultaneously in an opposing manner in FIG. **18**E. In FIG. **18**C, magnetic flux will only flow along path portions **448**B and **448**C of pole piece **444** causing resultant magnetic coupling forces depicted by arrows **456**, **458** which act to move permanent magnet control component **440** to the left, assuming armatures **454** are fixed. Similarly, due to the timing of subsequent coil energization resultant magnetic forces depicted by arrows **460**, **462** in FIG. **18**D and arrows **464**, **466** in FIG. **18**E act to continue movement of permanent magnet control component **440** to the left. Thus, if permanent magnet control component **440** were fixed to a device or structure, controlled movement of the device or structure along the path defined by armatures **454** could be achieved. Conversely, if permanent magnet control component **440** were fixed and armatures **454** were located on a device or structure, controlled movement of the device or structure could also be achieved. It is also easily recognized that by varying the coil energization sequence and timing relative movement in the opposite direction can be achieved. Further, if the permanent magnet was doughnut shaped and the armatures were arranged in a circumferential pattern, rotary motion would likewise be achievable.

Rotary Motion

One embodiment of a rotary motion device or motor **500** which incorporates various permanent magnet flux control aspects of the present invention is shown in the exploded view of FIG. **19** and in the partial assembled view of FIG. **20**. Motor **500** includes a rotor assembly which includes a shaft **502** and associated upper bearing **504**, a non-magnetic disk member **506** mounted for rotation with shaft **502**, and a rotor pole piece **508** which is mounted for rotation with disk member **506** such as by the use of screws **510**. Rotor pole piece **508** includes a ring-shaped portion having two inwardly extending magnetic flux path portions **512**A and **512**B. A stator assembly of motor **500** includes a doughnut or ring-shaped permanent magnet **514** having an upwardly directed north pole face positioned adjacent and in close proximity to rotor pole piece **508**, and a downwardly directed south pole face positioned adjacent and in contact with a stator pole piece **516**. Stator pole piece includes a ring-shaped portion having five inwardly projecting path portions **518**A–**518**E. Each path portion includes a respective winding post **520**A–**520**E extending therefrom and having a respective control coil **522**A–**522**E wound thereon. Stator pole piece faces **524**A–**524**E are positionable on respective winding posts **518**A–**518**B and, as shown in the partial assembly of FIG. **20**, are substantially aligned with the top surface of permanent magnet **514** so as to be positionable adjacent rotor path portions **512**A and **512**B when aligned therewith. Each of winding posts **518**A–**518**E and stator pole piece faces are formed of magnetic material, and although shown as separate pieces, an integral, one piece stator could be formed with similar winding posts and pole piece faces machined thereon. Lower bearing **526** is also shown.

FIGS. **21**A–**21**E illustrate top views of the partial assembly of FIG. **20** with magnetic flux shown. In FIG. **21**A magnetic flux travel when none of coils **522**A–**522**E are energized is depicted. Disregarding leakage flux, due to the low reluctance path provided by rotor pole piece path portions **512**A and **512**B, the majority of magnetic flux from the north pole face of permanent magnet **514** will travel radially inward along one of such path portions before passing downward through the stator assembly and returning to the south pole face of permanent magnet **514**. It is noted that rotor pole piece **508** includes two path portions and stator pole piece **516** includes five path portions such that rotor pole piece path portions **512**A and **512**B will always be skewed relative to the stator pole piece faces **524**A–**524**E. Only one rotor pole piece path portion can directly align with a stator pole piece face at a given time. By alternatingly energizing the control coils of each of the stator pole piece paths, rotary motion of the rotor may be achieved.

In particular, referring to FIGS. **21B–21D**, an energizing sequence which results in such rotary motion is described. In FIG. **21B**, control coils **522A** and **522C** are energized in a permanent magnet flux opposing manner. Permanent magnet magnetic flux traveling along rotor pole piece path portion **512A** tends to traverse to stator pole piece face **524B** causing a magnetic coupling force indicated by arrow **526**. Likewise, permanent magnet flux traveling along rotor pole piece path portion **512B** tends to traverse to stator pole piece face **524D** causing a magnetic coupling force indicated by arrow **528**. The result is rotation of rotor pole piece **508** in a clockwise direction as indicated by arrow **530**.

Referring to FIG. **21C**, just after rotor pole piece path portion **512B** is no longer aligned with stator pole piece face **524D**, control coil **522C** is de-energized and control coil **522D** is energized in an opposing manner such that the permanent magnet flux traveling along rotor pole piece path **512B** tends to traverse to stator pole piece face **524E** resulting in magnetic coupling force indicated by arrow **532**. Control coil **522A** remains energized such that a magnetic coupling force indicated by arrow **534** results. Accordingly, clockwise rotation of rotor pole piece **508** is continued.

In FIG. **21D**, just after rotor pole piece path portion **512A** is no longer aligned with stator pole piece face **524B**, control coil **522A** is de-energized and control coil **522B** is energized in a permanent magnet magnetic flux opposing manner such that the permanent magnet magnetic flux traveling along rotor pole piece path **512A** tends to traverse to stator pole piece face **524C** such that a magnetic coupling force indicated by arrow **536** results. Control coil **522D** remains energized such that a magnetic coupling force indicated by arrow **538** results, and clockwise rotation of rotor pole piece **508** is continued.

As shown in FIG. **21E**, just after rotor pole piece path portion **512B** is no longer aligned with stator pole piece face **524E**, control coil **522D** is de-energized and control coil **522E** is energized in a permanent magnet magnetic flux opposing manner such that the permanent magnet magnetic flux traveling along rotor pole piece path **512B** tends to traverse to stator pole piece face **524A** such that a magnetic coupling force indicated by arrow **540** results. Control coil **522B** remains energized such that a magnetic coupling force indicated by arrow **542** results, and clockwise rotation of rotor pole piece **508** is continued.

Thus, by alternating energizing and de-energizing control coils **522A–522E**, in a predetermined timed sequence based upon rotation of the rotor assembly, continued rotation movement of rotor pole piece **508** may be achieved. Such an energization/de-energization scheme can be achieved utilizing circuitry common in the art, such as the control circuitry described in Applicant's U.S. Pat. Nos. 5,463,263 and 5,455,474, as well as various of the circuit configurations described herein below. Referring now to FIG. **22**, an assembled view of rotary motor **500** is shown including a housing or cover formed by an upper housing member **544** and a lower housing member **546**, with portions of each housing member cut away to expose motor structure described above. It is recognized that such housing members **544** and **546** should be formed of a non-magnetic material, and likewise that motor shaft **502** and bearings **504**, **526** should be formed of a non-magnetic material.

In another embodiment, a rotary motion device or motor **580** in accordance with the present invention is shown in an exploded perspective view in FIG. **23** and in an assembled perspective view in FIG. **24**. Two spaced permanent magnets **582** and **584** are positionable between stator pole pieces **586** and **588**. Stator pole piece **586** includes two path portions **590A** and **590B** extending away from permanent magnets **582**, **584** in opposite directions. Likewise, stator pole piece **588** includes two path portions **592A** and **592B** extending away from permanent magnets **582**, **584** in opposite directions and alignable respectively with stator pole piece path portions **590A** and **590B**. Control coils **594**, **596**, **598**, and **600** are each positioned along a respective stator pole piece path portion as shown. A non-magnetic shaft **602** includes a pair of like elongated rotor members **604** and **606**, formed of magnetic material, mounted at spaced locations thereon and being angularly oriented with respect to each other, shaft **602** passing between spaced permanent magnets **582** and **584**. Non-magnetic end cap members **608** and **610** are attachable to the ends of stator pole pieces **586** and **588** and are configured for receiving shaft **602** and respective bearings **612** and **614**.

The ends of respective stator pole pieces **506** and **508** are configured for a given desired coupling relationship with rotor members **604** and **606**. For example, as shown in the exemplary end views of FIGS. **25A** and **25B**, with end cap **608** removed, the end of stator pole piece **586** may include an arcuate portion **616** which is configured to create a variable reluctance air gap **618** with elongate rotor member **604**. The end of stator pole piece **588** includes an arcuate portion **620** which is likewise configured to create a variable reluctance air gap **622** with rotor member **604**. In particular, portion **618** includes a circumferential curvature which has a center point offset below the axis of rotation of shaft **602** and rotor member **604** as indicated by circle **624** shown in shadow. Similarly, portion **620** includes a circumferential radius of curvature which has a center point offset above the axis of rotation of shaft **602** and rotor member **604**. When magnetic flux is passing along the path which includes a given end of the assembly, maximum coupling between the rotor member and stator pole pieces occurs when the rotor is positioned as shown in FIG. **25B**. Accordingly, the illustrated rotor member and stator pole piece configurations in and of themselves do not provide any skewing to the direction of rotation of the rotor assembly.

In this regard, various configurations for the rotor and ends of the stator pole pieces are shown in the end views of FIGS. **26–28**, which configurations provide skewing the direction of rotation. In particular, in device **620** of FIG. **26** a rotor member **622** having notches **624** and **626**, which notches provide for greater magnetic coupling with the stator pole pieces **628** and **630** at corners **632** and **634** such that rotation is skewed in the clockwise direction. If notches were instead located at corners **632** and **634**, skewed rotation in the counterclockwise direction would be the result. In device **620** such counterclockwise rotation could also be achieved by removing rotor **622** from shaft **636**, flipping it end to end, and replacing it on shaft **636**.

In the device **640** of FIG. **27**, a portion **642** of the arcuate end portion of stator pole piece **644** is removed and a portion **646** of the arcuate end portion of stator pole piece **648** is removed. This configuration results in greater magnetic coupling between rotor member **650** and stator pole piece **644** at corner **652**, and greater magnetic coupling between rotor member **650** and stator pole piece **648** at corner **654**, such that rotation is skewed in the counterclockwise direction. Clockwise rotation could be achieved by instead modifying the opposite side of stator pole pieces **644** and **648**.

FIG. **28** depicts an end view of a device **660** in which the axis **662** of the arcuate end portion of upper stator pole piece **664** and lower stator pole piece **666** is placed at an angle A as shown. This configuration creates an unequal variable reluctance air gap where opposite corners of rotor member **668** are closer to stator pole pieces **664** and **666**. Further, the angle at which maximum magnetic coupling between rotor member **668** and stator pole pieces **664** and **666** occurs is retarded by angle A. Rotation would be in the counterclockwise direction for the illustrated configuration.

Referring again to motor **580** of FIGS. **23–25**, rotary motion of such device is depicted in the end views of FIG. **29**A–**29**D. In each end view the end cap has been removed to show rotation of the rotor members and in each of FIGS. **29**A–**29**D an end view depicting rotor member **604** and an end view depicting rotor member **606** are shown side-by-side. In FIG. **29**A, rotor member **604** is defined as being at zero degrees and rotor member **606** is defined as being at ninety degrees. Control coils **594**, **598** are energized in a permanent magnet magnetic flux aiding manner such that no magnetic flux passes through stator pole piece path portions **590**B and **592**B. This allows rotor member **606** to move out of its ninety degree position and the magnetic coupling between rotor member **604** and stator pole piece path portions **590**A and **592**A will cause rotation to the position shown in FIG. **29**B and then FIG. **29**C. When rotor member **604** reaches the ninety degree position shown in FIG. **29**D control coils **594**, **598** are de-energized and control coils **596**, **600** are energized in a permanent magnet magnetic flux aiding manner causing rotation to continue due to the magnetic coupling between rotor member **606** and stator pole piece path portions **590**B and **592**B. Thus, by alternatingly energizing the control coils of each path with every ninety degree rotation of rotor members **604** and **606**, continuous rotary motion is achieved.

The initial direction of rotation can be controlled by the circuit means used to energize control coils **594**, **598** and **596**, **600**, which circuit means includes circuitry for detecting the angular position of the rotor members. In particular, if rotor members **604** and **606** are at rest in the position shown in FIG. **29**A, and coils **594**, **598** are energized in an aiding manner, rotation may be clockwise or counterclockwise. If the desired direction is clockwise but upon energization of coils **594**, **598** the rotor members begin to move counterclockwise, the detection circuitry will immediately de-energize coils **594**, **598** and energize coils **596**, **600** so that the counterclockwise direction is achieved.

Further, bypasses around permanent magnets **582** and **584** could be provided in rotary motion device **580**, such as those shown in FIG. **12**, and rotor members **604** and **606** could be formed by permanent magnets so as to take advantage of energizing the control coils in an exceeding manner.

A third embodiment of a rotary motion device or motor **650** is shown in the exploded partial perspective view of FIG. **30** and in the assembled partial perspective view of FIG. **31**. In motor **650** the stator assembly includes a control component **651** including a permanent magnet **652** having a stator pole piece **654** positioned adjacent one pole face thereof and a stator pole piece **656** positioned adjacent the opposite pole face thereof. Stator pole piece **654** includes a path portion **658**A extending to one side of permanent magnet **652** and a path portion **658**B extending to the one side thereof and spaced from first path portion **658**A. Control coils **660** and **662** are positioned along respective stator pole piece path portions **658**A and **658**B. Likewise, stator pole piece **656** includes path portions **664**A and **664**B which extend in a similar manner therefrom so as to be aligned with stator path portions **658**A and **658**B respectively. Control coils **666** and **668** are positioned along respective stator pole piece path portions **664**A and **664**B. Positioned opposite and facing control component **651** is a like control component **670** including permanent magnet **672**, stator pole piece **674** with path portions **676**A and **676**B having respective control coils **678** and **680**, and stator pole piece **682** with path portions **684**A and **684**B having respective control coils **686** and **688**. The end of each of the pole piece path portions **658**A, **658**B, **664**A, **664**B, **676**A, **676**B, **684**A, and **684**B is of a generally arcuate configuration.

A rotor assembly of motor **650** includes a non-magnetic shaft **700** having a permanent magnet rotor member **702** mounted thereon for rotation therewith. Permanent magnet rotor member **702** is generally ring-shaped and segmented to include distinct north and south pole faces which reverse about every ninety degrees therearound. When assembled the top and bottom surfaces of permanent magnet rotor member **702** align with pole pieces **654**, **656**, **674**, and **682** of the stator assembly and are preferably configured such that a minimal gap between the outer surface of permanent magnet rotor member **702** and the arcuate surfaces of the pole piece path portions is provided.

Rotation of device **650** can be achieved by controlled, timed energizing and de-energizing of control coils **660**, **662**, **666**, **668**, **678**, **680**, **686**, and **688**. Exemplary rotation is demonstrated with reference to the top views of FIGS. **32**A–**32**B which depict counterclockwise rotation of permanent magnet rotor member **702** through one-hundred eighty degrees. In FIG. **32**A stator pole piece path portion **658**A of component **651** is active and stator pole piece path portion **658**B is not active, which may be achieved by energizing control coil **660** in a permanent magnet magnetic flux aiding manner or by energizing control coil **662** in a permanent magnet magnetic flux opposing manner. Stator pole piece path portion **676**B of component **670** is active and stator pole piece path portion **676**A is not active, which may be achieved by energizing control coil **680** in a permanent magnet magnetic flux aiding manner or by energizing control coil **678** in a permanent magnet magnetic flux opposing manner. Thus, portions **690** and **692** of permanent magnet rotor member **702**, which both have a north magnetic polarity, will be repelled by the north polarity of stator pole piece path portions **658**A and **676**B aligned therewith. Portions **694** and **696** of permanent magnet rotor member **702**, both of which have a south magnetic polarity, will be attracted to the active path portions **658**A and **676**B. At the instant that rotor member portion **694** becomes aligned with stator pole piece path portion **658**A, as shown in FIG. **32**B, all coils are de-energized such that all pole piece path portions will be active as shown. Pole piece path portions **658**B and **676**A are then kept active while pole piece path portions **658**A and **676**B are made inactive. This is achieved by energizing control coils **662** and **678** in a permanent magnet magnetic flux aiding manner or by energizing control coils **660** and **680** in a permanent magnet magnetic flux opposing manner. Rotor member portions **690** and **692** will again be repelled by the north polarity of path portions **658**B and **676**A aligned therewith such that rotation of permanent magnet rotor **702** is continued. In FIG. **32**D all coils are shown de-energized when rotor portion **692** aligns with pole piece path portion **658**A. By continuing this timed sequence of energization and de-energization of the control coils, continued rotary movement is achieved. As explained above, the initial direction of rotation can be controlled by circuit means which detects the initial direction of permanent magnet rotor **702** and immediately alters the coil energization scheme if the initial direction is incorrect.

A side view of assembled motor **650** is shown in FIG. **33** and includes an upper housing or enclosure portion **710**, a bottom housing portion **712**, upper bearing **714**, and a lower bearing **716**.

A fourth embodiment of a rotary motion device or motor **740** is illustrated in FIGS. **34**–**39**. Motor **740** includes five stator control components **742**A–**742**E positioned around a ring shaped permanent magnet rotor member **744** (FIG. **36**). As shown with reference to component **742**A in FIG. **37** each stator component **742**A includes a permanent magnet **746**A with an upper pole piece **748**A positioned adjacent one pole face thereof and a lower pole piece **750**A positioned adjacent the opposite pole face thereof. Control coils **752**A, **754**A are positioned along respective pole pieces **748**A, **750**A. A bypass **756**A extends from pole piece **748**A to pole piece **750**A and is positioned between permanent magnet **746**A and control coils **752**A, **754**A. Alternatively, bypass **756**A could be provided on the opposite side of permanent magnet **746**A as shown in FIG. **38**. Although not shown, it is anticipated that permanent magnet rotor member **744** would be mounted on an axis for rotation therewith and that a motor housing or enclosure could be provided, such as shown in relation to motor **650** of FIG. **33**.

Referring to the top views of FIGS. **39**A–**39**D, rotary motion of rotor member **744** is depicted by the sequence of views. Regions **770** and **772** in FIGS. **39**A–**39**D represent the magnetic north regions of the top of permanent magnet rotor **744**. In FIG. **39**A control coils **752**E and **752**C are energized in a permanent magnet aiding and exceeding manner such that regions **770** and **772** of permanent magnet rotor **744** are repulsed by components **742**E and **742**C while permanent magnet motor regions **774** and **776** are attracted by components **742**E and **742**C. The resultant coupling forces act to move permanent magnet rotor in a counterclockwise direction to the location shown in FIG. **39**B. Just after permanent magnet rotor region **772** passes the point shown in FIG. **39**C, control coil **752**B is energized in a permanent magnet aiding and exceeding manner, while control coils **752**E and **752**C also remain energized, and counterclockwise rotation of permanent magnet rotor **744** is continued. Just after permanent magnet rotor region **772** passes by control component **742**C control coil **752**C is de-energized, while control coils **752**E and **752**B remain energized, so as to continue counterclockwise rotation. Then, just after permanent magnet rotor region **770** reaches the location shown in FIG. **39**D control coil **752**D is energized in a permanent magnet flux aiding and exceeding manner, while coils **752**E and **752**B remain energized, so as to continue counterclockwise rotation. Thus, as in the other embodiments, repeated and timed energization and de-energization of the control coils produces the desired rotational movement.

In terms of controlling the energization of coils in the devices described above, various electronic control circuit/switching means and electromechanical control circuit/switching machines are depicted in FIGS. **40**–**44**. In circuit **800** of FIG. **40** a given coil **802** is placed in series between an electrical energy source **804** and a power mosfet **806**. An LED **808** is connected to electrical energy source **804** through resistor **810** and is positioned to impinge upon a phototransistor **812** which is connected in series with resistor **814**. A control input of mosfet **806** is connected between phototransistor **812** and resistor. Accordingly, when LED **808** activates phototransistor **812** the voltage drop across resistor **814** activates, or turns ON, mosfet **806** and coil **802** is energized. Timed energization of coil **802** is provided by mounting an interrupter **816**, such as shown in FIG. **42**, to the shaft **816** of the motor device to be controlled, such that as interrupter **814** rotates with shaft **816** coil **802** is alternately energized and de-energized. In a device with a plurality of coils a corresponding plurality of LED/photoresistor pairs may be provided.

In circuit **820** of FIG. **41** a coil **822** is positioned between electrical energy source **824** and power mosfet **826**. A hall switch **828** is connected in series with resistor **830**. Hall switch **828** is also connected to the control input of mosfet **826** through resistor **832**. In a given device hall switch **828** would be positioned to react to a change in magnetic flux so as to control the ON/OFF switching of mosfet **826**, and thus the alternate energization and de-energization of coil **822**.

In FIG. **43** a circuit **840** for controlling two coils in an opposite manner is provided such that when coil **842** is energized coil **844** is de-energized, and such that when coil **842** is de-energized coil **844** is energized. Both coils **842** and **844** are connected in series between electrical energy source **846** and respective power mosfets **848** and **850**. An LED **852** and phototransistor **854** arrangement is provided, LED connected in series with resistor **856** and phototransistor connected in series with resistor **858**. When LED **852** turns phototransistor **854** ON the voltage drop across resistor **858** turns mosfet **848** ON and coil **842** is energized. At that time the voltage applied at the control input of mosfet **850** will be low and therefore mosfet **850** will be OFF and coil **844** will be de-energized. When interrupter **814** blocks LED **852**, phototransistor **854** is turned OFF and mosfet **848** is likewise turned OFF. The control input of mosfet **850** is therefore pulled high through resistor **860** and mosfet **850** is turned ON such that coil **844** is energized.

In a FIG. **44** a system **870** including member **872** mounted on rotating shaft **874** is provided, with the left side of member **872** being alternately conductive at **876** and non-conductive at **878**. Coils **880** and **882** are connected to respective brushes **884** and **886** which are positioned to contact member **872** during rotation thereof. Member **872** is connected through brush **890** to power supply **888**. Thus, coils **880** and **882** will alternatingly be energized and de-energized as the respective brushes thereof contact the conductive and non-conductive portions of member **872**.

Any of such circuit means, variations thereof, or other circuit means may be used to provide the timed energization of the control coils in the various embodiments of the present invention.

From the preceding description of the illustrated embodiments, it is evident that the objects of the invention are attained. Although the invention has been described and illustrated in detail, it is to be clearly understood that the same is intended by way of illustration and example only and is not to be taken by way of limitation.

For example, although the magnetic flux control techniques of the present invention have been discussed as applicable mainly to various motive applications, such magnetic flux control techniques are also useful in static applications.

Power Conversion

Referring to FIGS. **45**A–**45**C there is shown the permanent magnet device **900** of FIGS. **45**A–**45**C that has two magnetic flux paths provided by rectangular pole piece **902** which includes upper portion **904** and lower portion **906** each positioned against a respective pole face of permanent magnet **910**. Unlike the device of FIGS. **7**–**9**, fall away armatures are not provided. Rather, fixed armatures in the form of integral pole piece portions **912** and **914** extend from upper portion **904** to lower portion **906** completing the two flux paths in a permanent manner. Control coils **916**, **918** are provided along one flux path and control coils **920**, **922** are provided along the other flux path, such control coils acting as primary windings in device **900**. One coil **924** is positioned around pole piece portion **912** and another coil **926** is positioned around pole piece portion **914**, such coils **924**, **926** acting as secondary windings in device **900**.

In FIG. **45**A coils **916**, **918** are energized in a permanent magnet magnetic flux aiding manner so as to couple with all the magnetic flux of permanent magnet **910**. All magnetic flux flows along path **930** as shown and thus couples with coil **924**. In FIG. **45**B no coils are energized and the permanent magnet magnetic flux splits evenly between paths **930** and **932**, coupling with both coil **924** and coil **926**. In FIG. **45**C coils **920**, **922** are energized in a permanent magnet magnetic flux aiding manner such that all magnetic flux traverses path **932** and couples with coil **926**. In FIG. **45**D no coils are energized as in FIG. **45**B. By continuously alternatingly energizing and de-energizing coils **916**, **918** and **920**, **922** in such a manner energy conversion is achieved due to the coupling with coils **924** and **926**. The magnetic flux in the integral pole piece portions **912** and **914**, and thus the flux coupling with respective coils **924** and **926**, varies by a factor of twice the amount of magnetic flux generated by energizing coils **916**, **918** and **920**, **922**.

The construction shown in FIGS. **45**A and **45**X are similar to the construction shown in FIGS. **7** and **47**. The difference in both cases relates to replacing the two flux paths and armatures with one continues flux path. The arrangement in FIG. **7** has one permanent magnet and four coils and the arrangement in FIG. **47** has two permanent magnets and two coils. Although the physical aspects of the two arrangements and the details of the flux control vary, the control method for varying the permanent magnets flux are similar and will be described simultaneously and only differences will be pointed out.

With continuous flux paths the static flux from the permanent magnet or magnets is useless. However, if the static flux of the permanent magnet confined to the flux paths were modified to be time varying it would have utility for electromagnetic induction devices for power conversion like transformers and power inverters. However, the same basic method for controlling the flux of a permanent magnet to provide linear and rotary motion can also be applied to time varying the static flux from the permanent magnetic. The construction shown in FIG. **45**X utilizes four control coils and a single permanent magnet and the construction shown in FIG. **45**A uses two control coils and two permanent magnets. The flux that would normally be supplied by a primary winding is supplied by the static flux of the permanent magnet or magnets and the control coils convert this static flux into a time varying flux in a novel way. Both arrangements use two secondary coils, the secondary coils are placed in the region of the continuous flux path that would be occupied by an armature or rotor in the linear or rotary arrangements. The regions of the flux paths that perform work are the same in all cases.

In all cases the control coils can either be wired in series or parallel and the secondary coils can be either wound in series or parallel. More than one secondary coil or secondary coils with multiple taps can be placed in the working regions and further multiple flux paths can be utilized with one or more secondary coils placed in each of the working regions. This is made obvious by the disclosures of the linear and rotary devices herein and based on the fact that the working regions of the flux paths are identical.

FIGS. **45**X and **45**A also show the paths of the static flux of the permanent magnet or magnets when no current is flowing in the control coils. In the arrangement shown in FIG. **45**X the flux from the single permanent magnet divides between the two working areas of the flux path. In the arrangement of FIG. **45**A all of the flux of one of the permanent magnets passes through one of the working regions and all of the flux of the second permanent magnet passes through the other working region. Each of the working regions in both cases are occupied by secondary coils.

FIGS. **45**Y and **45**B show the control coils energized with the polarity shown with respect to the polarity of the permanent magnet or magnets included. In FIG. **45**Y the opposing coil blocks the passage of flux from the permanent magnet and the aiding coil couples with the flux of the permanent magnet and therefore all of the flux of the permanent magnet passes through one working region as shown. In FIG. **45**A the opposing side of the coil blocks the passage of flux from the permanent magnet on the opposing side of the coil and the aiding side of the coil couples with the flux of the other permanent magnet and therefore all of the flux of both the permanent magnets passes through the working region as shown.

FIGS. **45**Z and **45**C show the control coils energized with a polarity opposite of that shown in FIGS. **45**Y and **45**B. The same action occurs and results in all of the permanent magnet or magnets path flux passing through the opposite working regions.

By alternating the polarity of the control coils during one cycle, one working region experiences an increasing flux and the opposite region experiences a decreasing flux and during the next cycle the opposite occurs. This results in the induction of a voltage in the secondary coils that is decided by the magnitude of the change in flux in the working region and the time in which this change occurs. The novelty of this discovery is that the primary flux inducing the voltage in the secondary coils is supplied by the permanent magnet or magnets and is far greater than the flux supplied by the control coils.

Further, in the rotary motion devices of FIGS. **31** and **34**, it is not necessary that respective rotor members **702** and **744** be formed of permanent magnets. Each could take the form shown in FIG. **46** where sections **950** and **952** are formed of magnetic material such as soft iron and sections **954** and **956** are formed by a non-magnetic filler material.

FIGS. **47** and **48** show another embodiment **1000** of the subject device. The embodiment **1000** includes two spaced permanent magnets **1002** and **1004** each of which has its north pole adjacent the upper surface and its south pole adjacent the lower surface. A magnetizable bridging member **1006** extends across and makes contact with the north magnetic poles of the magnets **1002** and **1004** and another magnetizable bridging member **1008** makes contact with the south magnetic poles of the two permanent magnets **1002** and **1004**. The members **1006** and **1008** extend slightly beyond the opposite sides of the respective permanent magnets **1002** and **1004** and a pair of spaced armature members **1010** and **1012** are positioned to move into and out of engagement with the ends of the members **1006** and **1008**. Coils **1014** and **1016** are mounted respectively on the members **1006** and **1008** in the space between the permanent magnets **1002** and **1004**, and the armatures **1010** and **1012** are shown connected together by a rod **1018** which enables them to move backwards and forwards into engagement with the respective members **1006** and **1008** when different voltages are applied to the respective coils **1014** and **1016**. In FIGS. **47**, the coils **1014** and **1016** are energized as shown with the coil **1014** having its north magnetic end to the left and its south magnetic end to the right and the opposite is true of the coil **1016**. In FIG. **48**, the voltage applied to the respective coils **1014** and **1016** is reversed so that the polarity of the left end of coil **1014** is south and the polarity of the opposite end of the same coil **1014** is a north magnetic pole. The reverse is true of the coil **1016**. It is to be noted in FIGS. **47** and **48** that the relationship of aiding and opposing is indicated on the figures to indicate the relationship when the coils are energized. For example, in FIG. **47** when the coils are energized as shown the relationship is opposing for the permanent magnet **1002** and is aiding with respect to the permanent magnet **1004**. The reverse is true when the voltage on the coils is reversed as shown in FIG. **48**. By properly timing the voltage on the respective coils the movement of the armature is controlled. The same principles can be applied to produce rotating movement as shown in FIG. **42**.

FIG. **49** shows another embodiment **1030** of the subject invention using principles similar to those described in connection with FIGS. **47** and **48**. The embodiment **1030** includes a plurality, three being shown, of stationary members **1032**, **1034** and **1036**. The details of these members are better shown in FIG. **50** which shows the details of the member **1036**. This member includes a pair of permanent magnets **1038** and **1040**, each of which has magnetizable members mounted adjacent opposite sides thereof as in the previous construction. The members **1042** and **1044** also have coils **1046** and **1048**, respectively, and the coils are energized as described in connection with FIGS. **47** and **48** to produce aiding and opposing magnetism. The construction shown in FIG. **49** may have three stator portions as shown or it may have more stator portions as desired. The rotor **1050** is positioned in the space between the members **1032**, **1034** and **1036** and includes a permanent magnet portion part of which has its north magnetic pole on the surface as shown and the other parts has its south magnetic pole in the same surface as shown. The permanent magnets **1038** and **1040** on the stators interact with the permanent magnets on the rotor to produce the rotating motion and is controlled by the energizing of the coils.

Other applications and advantages of the devices and methods of the present invention exist and various modifications are possible, and therefore the present invention is not intended to be limited to the specific examples disclosed herein. Accordingly, the spirit and scope of the invention are to be limited only by the terms of the appended claims.

What is claimed is:

1. A permanent magnet device, comprising a permanent magnet having north and south pole faces, a first pole piece, a second pole piece, a first control coil, a second control coil, and circuit means, the first pole piece positioned adjacent the north pole face of the permanent magnet and including a first path portion, a second path portion and a third portion, the first path portion extending beyond a perimeter of the north pole face in one direction and the second path portion extending beyond the perimeter of the north pole face in another direction to define first and second flux paths for magnetic flux emanating from the north pole face of the permanent magnet, the first path portion of the first pole piece connected to the second path portion of the first pole piece by the third portion which extends across the north pole face of the permanent magnet, the second pole piece positioned adjacent the south pole face and including a first path portion and a second path portion, the first path portion extending beyond a perimeter of the south pole face and substantially aligned with the first path portion of the first pole piece, the second path portion extending beyond the perimeter of the south pole face and substantially aligned with the second path portion of the first pole piece, the first control coil positioned around the first path portion of the first pole piece, the second control coil positioned around the second path portion of the first pole piece, the circuit means connected to each of the first control coil and the second control coil to alternatingly energize the first coil and the second coil in a timed sequential manner.

2. The permanent magnet device as set forth in claim **1**, wherein the first control coil and the second control coil are alternatingly energized in a permanent magnet magnetic flux aiding manner.

3. The permanent magnet device as set forth in claim **1**, wherein the first control coil and the second control coil are alternatingly energized in a permanent magnet magnetic flux opposing manner.

4. The permanent magnet device as set forth in claim **1**, further comprising a rotor member mounted on a shaft for rotation therewith, the rotor member sized, shaped, and positioned to extend substantially from the first path portion of the first pole piece to the first path portion of the second pole piece during at least some part of its rotation.

5. The permanent magnet device as set forth in claim **4**, wherein the rotor member is formed by at least one permanent magnet.

6. The permanent magnet device as set forth in claim **1**, wherein the second path portion of the first pole piece and the second path portion of the second pole piece are positioned alongside the first path portion of the first pole piece and the first path portion of the first pole piece.

7. The permanent magnet device as set forth in claim **1**, further comprising a first bypass extending from the first path portion of the first pole piece to the first path portion of the second pole piece, one end of the first bypass positioned adjacent the first path portion of the first pole piece and between the permanent magnet and the first control coil.

8. The permanent magnet device as set forth in claim **6**, further comprising a second bypass extending from the second path portion of the first pole piece to the second path portion of the second pole piece, one end of the second bypass positioned adjacent the second path portion of the first pole piece and between the permanent magnet and the second control coil.

9. The permanent magnet device as set forth in claim **1**, further comprising a plurality of armatures arranged to define a path of movement, wherein the second path portion of the first pole piece and the second path portion of the second pole piece are positioned alongside the first path portion of the first pole piece and the first path portion of the second pole piece, and wherein all of such pole piece path portions include an end face positioned adjacent the path of movement defined by the plurality of armatures.

10. The permanent magnet device as set forth in claim **1**, wherein the first control coil and the second control coil are simultaneously energized one in a permanent magnet magnetic flux aiding manner and one in a permanent magnet magnetic flux opposing manner.

11. The permanent magnet device as set forth in claim **1**, further comprising two shaft connected armatures positionable adjacent the ends of the first and second pole pieces, wherein each of the armatures is formed by a permanent magnet.

12. The permanent magnet device of claim **1** further comprising a first fixed armature extending between the first path portion of the first pole piece to the first path portion of the second pole piece and a second fixed armature extending between the second path portion on the first pole piece to the second path portion of the second pole piece.

13. The permanent magnet device of claim **12** where a first secondary coil is wrapped around the first fixed armature and a second secondary coil is wrapped around the second fixed armature.

14. The permanent magnet device of claim **13** including circuit means connected to the control coils to control the energizing thereof to produce a varying flux in the armatures and to induce voltage in the secondary coils.

15. The permanent magnet device of claim **1** wherein there are at least two permanent magnets each having north and south pole faces, the first pole piece being positioned extending between the north pole faces of the permanent magnets and the second pole piece positioned extending between adjacent south pole faces of the permanent magnets.

16. A method for controlling the path of magnetic flux from a permanent magnet, the method comprising the steps of:

(a) placing a first pole piece adjacent a first pole face of the permanent magnet so as to have at least first and second path portions extending beyond a perimeter of the first pole face;

(b) placing a second pole piece adjacent a second pole face of the permanent magnet so as to include at least one portion which substantially aligns with the first and second path portions of the first pole piece;

(c) placing a first control coil along and around the first path portion of the first pole piece;

(d) placing a second control coil along and around the second path portion of the first pole piece;

(e) repeatedly energizing the first control coil in a permanent magnet magnetic flux opposing manner so as to prevent magnetic flux of the permanent magnet from traversing the first path portion of the first pole piece; and

(f) repeatedly energizing the second control coil in a permanent magnet magnetic flux opposing manner so as to prevent magnetic flux of the permanent magnet from traversing the second path portion of the first pole piece.

17. The method as set forth in claim **16** wherein the energization of steps (e) and (t) take place in a simultaneous manner.

18. A method for controlling the path of magnetic flux from a permanent magnet, the method comprising the steps of:

(a) placing a first pole piece adjacent a first pole face of the permanent magnet so as to have at least first and second path portions extending beyond a perimeter of the first pole face;

(b) placing a second pole piece adjacent a second pole face of the permanent magnet so as to include at least one portion which substantially aligns with the first and second path portions of the first pole piece;

(c) placing a first control coil along and around the first path portion of the first pole piece;

(d) placing a second control coil along and around the second path portion of the first pole piece; and

(e) alternatingly performing the following steps in a repeated manner:

(i) energizing the first control coil in a permanent magnet magnetic flux aiding manner so as to couple with substantially all magnetic flux of the permanent magnet such that substantially no magnetic flux of the permanent magnet traverses the second path portion of the first pole piece when the first control coil is so energized; and

(ii) energizing the second control coil in a permanent magnet magnetic flux opposing manner so as to couple with substantially all magnetic flux of the permanent magnet such that substantially no magnetic flux of the permanent magnet traverses the first path portion of the first pole piece when the second control coil is so energized.

19. A method for controlling the path of magnetic flux from a permanent magnet the method comprising the steps of:

(a) placing a first pole piece adjacent a first pole face of the permanent magnet so as to have at least first and second path portions extending beyond a perimeter of the first pole face;

(b) placing a second pole piece adjacent a second pole face of the permanent magnet so as to include at least one portion which substantially aligns with the first and second path portions of the first pole piece;

(c) placing a first control coil along and around the first path portion of the first pole piece;

(d) placing a second control coil along and around the second path portion of the first pole piece; and

(e) alternatingly performing the following steps in a repeated manner:

(i) simultaneously energizing the first control coil in a permanent magnet magnetic flux aiding manner and the second control coil in a permanent magnet flux opposing manner; and

(ii) simultaneously energizing the first control coil in a permanent magnet flux opposing manner and the second control coil in a permanent magnet magnetic flux aiding manner.

20. A rotary motion device, comprising a rotor assembly including a shaft which defines an axis of rotation of the assembly, a rotor pole piece mounted for rotation with the shaft, the rotor pole piece including an outer ring portion having at least two path portions extending inwardly from a periphery of the outer ring portion;

a stator assembly including a permanent magnet having a generally ring-shaped configuration, a first pole face of the permanent magnet positioned adjacent the outer ring portion of the rotor pole piece, the stator assembly further comprising a stator pole piece including an outer ring portion positioned adjacent a second pole face of the permanent magnet and having a plurality of path portions extending inwardly from the periphery, each path portion further including a respective portion which extends toward a plane defined by the first pole face of the permanent magnet and alignable with each of the rotor pole piece path portions at certain rotational positions of the rotor pole piece, each path portion including a control coil positioned therealong;

and circuit means connected to each of the coils and including a source of electrical energy and switch means for energizing respective ones of the control coils in a predetermined timed sequence based upon rotation of the rotor assembly.

21. A rotary motion device, comprising:

a rotor assembly including a shaft which defines an axis of rotation of the assembly, a pair of spaced elongated rotor members mounted on the shaft at spaced locations thereon and angularly oriented with respect to each other, each of the elongated rotor members formed of a magnetic material;

a stator assembly including a permanent magnet having opposed first and second pole faces, a first pole piece positioned adjacent the first pole face and a second pole piece positioned adjacent the second pole face, each pole piece including a respective first path portion extending beyond a perimeter of its adjacent pole face and having an arcuate shaped end portion, the first path portion of the first pole piece aligned with the first path portion of the second pole piece, each pole piece further including a respective second path portion extending beyond the perimeter of its adjacent pole face in a direction opposite to that of the first path portions and having an arcuate shaped end portion, the second path portion of the first pole piece aligned with the second path portion of the second pole piece, at least one of the first path portions of the first pole piece and the first path portion of the second pole piece including a control coil mounted on at least one of the pole pieces, at least one of the second path portions of the first pole piece and the second path portion of the second pole piece including a control coil mounted on at least one of the pole pieces,

wherein the rotor assembly extends from end to end of the stator assembly such that the elongate members are aligned with the arcuate shaped end portions of the path portions of the pole pieces;

and circuit means connected to each of the coils and including a source of electrical energy and switch means for energizing respective ones of the control coils in a predetermined timed sequence based upon rotation of the rotor assembly.

22. A rotary motion device comprising:

a rotor assembly including a shaft which defines an axis of rotation of the assembly, a ring-shaped rotor member mounted for rotation with the shaft, the ring-shaped rotor member including a plurality of distinct circumferential regions;

a stator assembly including a first permanent magnet, a first pole piece positioned against a first pole face and a second pole piece positioned against a second pole face, the first pole piece including at least a first path portion extending beyond a perimeter of the first pole face, the second pole piece including at least a first path portion extending beyond a perimeter of the second pole face, the first path portion of the first pole piece aligned with the first path portion of the second pole piece, at least a portion of the ring-shaped rotor member positioned between the first path portion of the first pole piece and the first path portion of the second pole piece, at least one of the first path portions of the first pole piece and the first path portion of the second pole piece including a first control coil positioned at a point intermediate the first permanent magnet and the ring-shaped rotor member;

and circuit means connected to the first control coil and including a source of electrical energy and switch means for energizing the first control coil in a predetermined timed manner based upon rotation of the rotor assembly.

23. The rotary motion device as set forth in claim **22**, wherein the ring-shaped rotor member is formed by a permanent magnet having distinct circumferential regions of opposite polarity.

24. The rotary motion device as set forth in claim **23**, wherein the first pole piece includes a second path portion spaced from and extending adjacent to the first path portion, the second pole piece including a second path portion spaced from and extending adjacent to the first path portion such that the second path portion of the first pole piece is aligned with the second path portion of the second pole piece, at least a portion of the ring-shaped permanent magnet rotor member positioned between the second path portion of the first pole piece and the second path portion of the second pole piece, at least one of the second path portions of the first pole piece and the second path portion of the second pole piece having a second control coil mounted on at least one of the pole pieces at a point intermediate the first permanent magnet and the ring-shaped permanent magnet rotor member, the second control coil connected to the circuit means so as to be energized in a predetermined timed manner based upon rotation of the rotor assembly.

25. The rotary motion device as set forth in claim **22**, wherein the stator assembly further comprises a second permanent magnet, a third pole piece positioned adjacent a first pole face of the second permanent magnet and a fourth pole piece positioned adjacent a second pole face of the second permanent magnet, the third pole piece including at least a first path portion extending beyond a perimeter of the second permanent magnet first pole face, the fourth pole piece including at least a first path portion extending beyond a perimeter of the second permanent magnet second pole face, the first path portion of the third pole face aligned with the first path portion of the fourth pole piece, at least a portion of the ring-shaped permanent magnet rotor member positioned between the first path portion of the third pole piece and the first path portion of the fourth pole piece, at least one of the first path portions of the third pole piece and the first path portion of the fourth pole piece including a third control coil mounted on at least one of the pole pieces at a point intermediate the second permanent magnet and the ring-shaped permanent magnet rotor member, the third pole piece including a second path portion spaced from and extending adjacent to the first path portion the fourth pole piece including a second path portion spaced from and extending adjacent to the first path portion thereof such that the second path portion of the third pole piece is aligned with the second path portion of the fourth pole piece, at least a portion of the ring-shaped permanent magnet rotor member positioned between the second path portion of the third pole piece and the second path portion of the fourth pole piece, at least one of the second path portions of the third pole piece and the second path portion of the fourth pole piece including a fourth control coil mounted on at least one of the pole pieces at a point intermediate the second permanent magnet and the ring-shaped permanent magnet rotor member, wherein each of the third and fourth control coils are connected to the circuit means so as to be energized in a predetermined timed manner based upon rotation of the rotor assembly.

26. A device for producing rotary motion comprising:

a rotor assembly including a shaft which defines an axis of rotation for the assembly, a ring-shaped rotor member mounted for rotation with the shaft, the ring-shaped rotor member having a plurality of distinct circumferentially positioned regions extending around the axis, a stator assembly including a first permanent magnet, a first pole piece positioned against the first pole face of the first pole piece and a second pole piece positioned against a second pole face of the first pole piece, the first pole piece including at least a first path portion extending beyond a perimeter of the first pole face, the second pole piece including at least a first path portion extending beyond the perimeter of the second pole face, the first path portion of the first pole piece aligned with the first path portion of the second pole piece, at least a portion of the ring-shaped rotor member positioned between the first path portion of the first pole piece and the first path portion of the second pole piece, at least one of the first path portions of the first pole piece and the first path portion of the second pole piece including a first control coil mounted on at least one of the pole pieces at a point intermediate the first permanent magnet and the ring-shaped rotor member; and circuit means connected to the first control coil and including a source of electrical energy and switch means for energizing the first control coil in a predetermined timed manner based upon position of the rotor assembly during rotation of the rotor assembly.

27. The device for producing rotary motion of claim **26** wherein the circuit means includes means for timing the energizing of the first control coil includes means for adjusting the timing thereof.

28. The device for producing rotor motion of claim **26** including means to vary the flux generated in the first and second pole pieces.

29. A device for handling the flux between two separate permanent magnets each of which has a north magnetic pole adjacent one side face and the south magnetic pole adjacent to the opposite side face, the north and south side pole faces respectively of both magnets being substantially in alignment, a first member in surface-to-surface contact with the north magnetic faces of the spaced permanent magnets, a second member in surface-to-surface contact with the south magnetic faces of the spaced permanent magnets, first and second armatures each positioned adjacent opposite ends of the first and second permanent magnets and adjacent to opposite ends of the spaced members, a coil mounted on each of the members in the space between the adjacent permanent magnets, and means for applying voltages of predetermined polarities across the respective coils to change the magnetic coupling between the permanent magnets and between the armatures.

30. A device for producing rotational movement comprising:

a rotor having a shaft rotatable about the axis thereof, a member constructed of permanent magnets mounted on the shaft, said member having circumferential portions some of which have a north magnetic pole and others a south magnetic pole adjacent to the same side thereof, the opposite surface of the permanent magnet member having north magnetic poles opposite the south magnetic poles and south magnetic poles opposite the north magnetic poles, a stator having a plurality of circumferentially spaced portions each of which includes at least one permanent magnet and a pair of members mounted adjacent opposite sides of the permanent magnets, the members being positioned adjacent to the periphery of the rotor permanent magnet member and means on the member adjacent each opposite side of the stator permanent magnet for mounting a coil, and means for energizing the coil on each stator portion in sequence to produce magnetic coupling force between the stator and the rotor in a direction to produce rotating motion of the rotor.

31. A device including a rotating member and a stationary member, each having a permanent magnet portion positioned to produce magnetic coupling force therebetween in predetermined positions thereof, the rotor including a shaft rotatable about its axis and the permanent magnet extending around the shaft and formed by a plurality of adjacent portions of permanent magnet material whereby adjacent portions have their north and south magnetic pole faces on opposite sides of the rotor permanent magnet, a plurality of stator members each stator member having at least one permanent magnet having a north magnetic pole adjacent one side and a south magnetic pole adjacent to the opposite side, a pair of members positioned adjacent respective opposite sides of the stator permanent magnet in position to extend to adjacent the rotor permanent magnet whereby a flux path is formed between the members and the stator and rotor permanent magnets, a coil mounted on each member of the stator and means for applying a voltage of predetermined polarity to each of said coils to control the flux through a path between the permanent magnets and to control the coupling force between the permanent magnets on the stator and the permanent magnets on the rotor.

32. A motion producing device comprising at least one permanent magnet having a north pole opposite and spaced from a south pole, a pair of spaced substantially parallel members adjacent respectively the north and south poles of the at least one permanent magnet and extending outwardly to substantially aligned opposite edges, a flux supporting member positioned adjacent the respective opposite edges of each pair of parallel members, a coil on selected ones of the parallel members, and a source of electrical energy connected to each of the coils for energizing the coils to change the flux in the parallel members and in the flux supporting members.

33. The motion producing device of claim **32** wherein there are at least two spaced permanent magnets extending between the parallel members.

34. The motion producing device of claim **32** wherein one of said pair of parallel members is subdivided into a plurality of sidewardly extending portions extending to one of said opposite side edges, at least one of said coils being positioned on at least one of said sidewardly extending portions.

35. The motion producing device of claim **34** wherein there are coils on a plurality of respective ones of the sidewardly extending portions.

36. The motion producing device of claim **32** wherein the permanent magnet and the parallel members are annular in shape.

37. The motion producing device of claim **32** including a by-pass member extending between the pair of spaced substantial parallel members adjacent one side of the permanent magnet.

38. A permanent magnet device comprising at least two permanent magnets each having north and south pole faces, a first pole piece, a second pole piece, a first control coil, a second control coil and circuit means, the first pole piece positioned adjacent the north pole faces of the at least two permanent magnets and including a first path portion, a second path portion and a third path portion, the first path portion extending beyond the perimeter of the north pole faces and the second path portion extending beyond the perimeter of the north pole faces to define first and second flux paths for magnetic flux emitting from the north pole faces of the at least two permanent magnets, the first path portion of the first pole piece connected to the second path portion of the first pole piece by a third portion which extends across the north pole face of the at least two permanent magnets, the second pole piece positioned adjacent to the south pole faces of the at least two permanent magnets and including a first path portion and a second path portion, the first path portion extending beyond a perimeter of the south pole faces and substantially aligned with the first path portion of the first pole piece, the second path portion extending beyond the perimeter of the south pole faces and substantially aligned with the second path portion of the first pole piece, the first control coil positioned around the first path portion of the first pole piece, the second control coil positioned around the second path portion of the first pole piece, and the circuit means connected to each of the first control coil and the second control coil to alternatingly energize the first coil and the second coil in a timed sequential manner.

39. The permanent magnet device of claim **38** further comprising a first fixed armature extending between the first path portion of the first pole piece to the first path portion of the second pole piece and a second fixed armature extending between the second path portion of the first pole piece to the second path portion of the second pole piece.

40. The permanent magnet device of claim **39** where a first secondary coil is wrapped around the first fixed armature and a second secondary coil is wrapped around the second fixed armature.

41. The permanent magnet device of claim **40** including circuit means connected to the control coils to control the energizing thereof to produce a varying flux in the armatures and to induce voltage in the secondary coils.

42. The permanent magnet device of claim **38** wherein there are at least two permanent magnets each having north and south pole faces, the first pole piece being positioned extending between the north pole faces of the permanent magnets and the second pole piece positioned extending between the south pole faces of the permanent magnets.

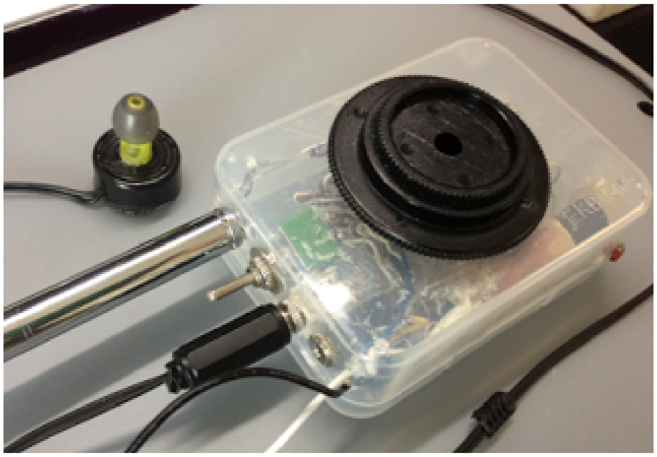
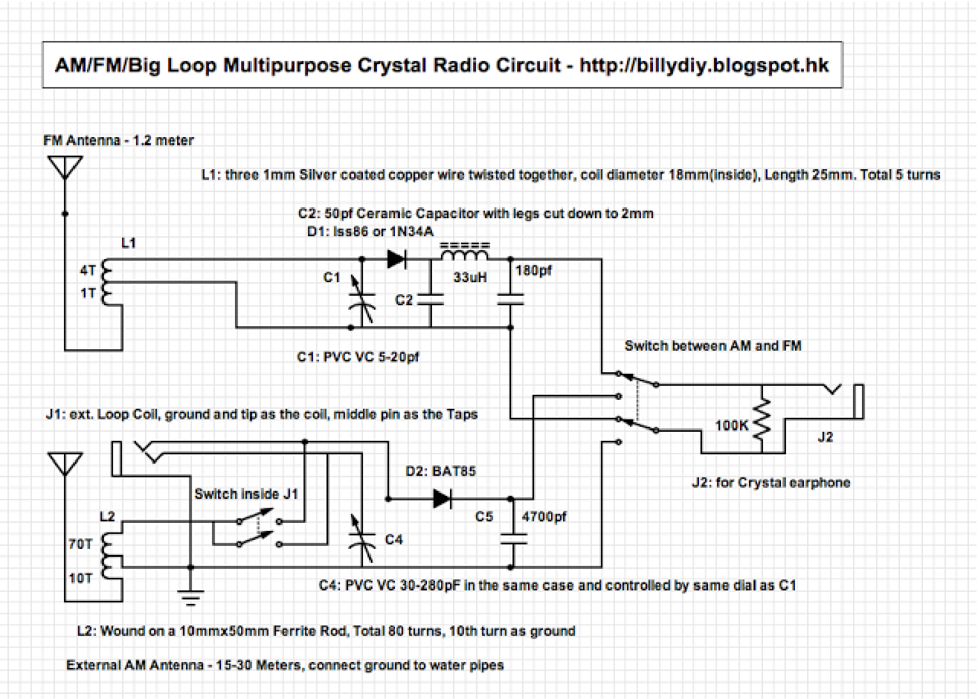
AM/FM/Loop Crystal Radio



[http://3.bp.blogspot.com/-W5MoCILOqOU/Uc2WU1CTbbI/AAAAAAAABNA/hH64_FNxMpo/s436/Screen+Shot+2013-06-23+at+12.06.23+PM.png]

Build a multifunction battery free crystal radio to listen to either AM or FM radio.
You can also use the same radio to connect to a bigger loop coil to get stronger signal for the AM radio instead of relying on the smaller AM coil inside the radio.

Parts you will need:
A Diode that works in high frequency (200Mhz or above, e.g. AA112, 1N34A, 1N48, Iss86 or Iss106.
A Diode that work in AM frequency e.g 1N34A, 1N60, BAT85.
A quadruple PVC Variable capacitor with one end for 2x 20pf, the other end for 2x 140pf.
50pf and 180pf fixed ceramic capacitor
100K 1/4W resistor
33uH Choke coil.
AM radio coil - ferrite rod
3.5mm mono headphone jack
3.5mm stereo headphone jack with internal switches (for selecting whether to use the external big loop or the internal coil for AM.
A 2 by 3 switch to select AM or FM.
A high impedance 4K Ohm earphone or a crystal earphone.



AM/FM/Big Loop Multipurpose Crystal Radio Circuit - http://billydiy.blogspot.hk
FM Antenna - 1.2 meter
L1: three 1mm Silver coated copper wire twisted together, coil diameter 18mm(inside), Length 25mm. Total 5 turns
C2: 50pf Ceramic Capacitor with legs cut down to 2mm
D1: Iss86 or 1N34A

General George O. Squier

***Scientific American* (July 14, 1919, p. 624) ~**

"With Trees For Ears"

A Wireless Station Within the Reach of Everybody

With a pair of receives to his ears, an amazed visitor to a certain radio station heard a high-toned hum which changed to a low growl, then skied to the upper reaches of the musical scale in a

faint, very faint buzz, as if some microscopic mosquito had had his song made audible. The operator rapidly rapidly turning the knobs on his couplers and condensers, raised his hand: suddenly, through the changing radio signals which were clamoring for attention together in the receivers came his voice; "There --- the loud, easily heard one is New Brunswick; the fainter, lower one is Nauen, in Germany".

If all this had taken place in the great Arlington station one would not have wondered, save perhaps at the inability to tune out all radio but Nauen. But it was a little portable house erected in thick woods near the edge of the District of Columbia and the signals were received through an oak tree for an antenna.

It is not a joke nor a scientific curiosity, this strange discovery of Gen. George O. Squire, Chief Signal Officer, that trees --- all trees, of all kinds and all heights, growing anywhere --- are nature's own wireless towers and antenna combined. The matter first came to his attention in 1904, through the use of trees as grounds for Army buzzer and telegraph and telephone sets, which, in perfectly dry ground and in a dry season, functioned poorly or not at all with ordinary grounds. Right then he began experiments with a view to seeing what possibilities, if any, the tree had as an aerial. But in 1904 radiotelegraphy was far more undeveloped than at present, and vacuum amplifying tubes were not thought of.

During the war the Signal Corps established a chain of special receiving stations in different localities to copy and record enemy and allied radio messages. Some of those stations were instructed to test the efficiency of growing trees as receiving antennae.

With the remarkably sensitive amplifiers now available, it was not only possible to receive signals from all the principle European stations through a tree, but it has developed beyond a theory and to a fact that a tree is as good as any man-made aerial, regardless of the size or extent of the latter, and better in the respect that it brings to the operator's ears far less static interference.

This is a rather broad statement, yet there beyond the Capital of the nation stands a little portable house, the oak tree, a small receiving set and a couple of enlisted men and an officer on duty; and the curious may, with permission, hear for themselves that the signals so received are neither faint not interrupted, but strong, full-toned dots and sashes even when they come from far-off Nauen. Page after page is copied daily from the propaganda material which Nauen sends out by the ream. Lyons, Poldhu, ships at sea, even the NC-4 on her way, are heard plainly. As for New Brunswick or nearby Arlington --- they deafen the listener if he is unwise enough to try to "take" them otherwise than with the phones lying on the tables.

It will puzzle the amateur as it has puzzled the experts, how a tree, which is certainly well grounded, can also be an insulated aerial. The method of getting the disturbances in potential from treetop to instrument is so simple as to be almost laughable. One climbs a tree to two-thirds of its height, drives a nail a couple of inches into the tree, hangs a wire therefrom, and attaches the wire to the receiving apparatus as if it were a regular lead-in from a lofty copper or aluminum aerial. Apparently some of the etheric disturbances passing from treetop to ground through the tree are diverted through the wire --- and the thermionic tube most efficiently does the rest.

It is interesting to learn that the tree behaves very much like any other aerial; it receives better in dry clear weather than in muggy, damp weather. It plucks messages from the ether more clearly at night than in the day. It is affected very little by rain. It is affected not at all by the presence of other trees; so far as has yet been ascertained it makes little difference whether one drives his nail in a tree in the forest or a lone tree on the plain. Certainly it makes no difference that amounts to anything whether the tree be just an ordinary tree or a giant; it was a 60-foot oak over which the very awe-struck correspondent heard Nauen telling a waiting world what good people the Germans really are. And to prove that it made no particular difference what kind of tree was used the officer in charge switched to a pine tree, which received equally well.

A dead tree will not do, and a tree not in leaf is not so sensitive as one in full foliage. It makes much difference where the nail is driven. General Squier calls the proper place the optimum point, and experimentally it has been determined that two-thirds of the distance from ground to top is the best place -- in a 60-foot tree, 40 feet from the ground.

One nail is sufficient, and it may be any kind of nail; but copper is preferred as not rusting. In practice, if a tree station is to be at all permanent, several nails would be driven and connected to the same wire, each additional nail up to 6 or 8 making the diverted current a little stronger. But 40 nails apparently produce no clearer signals than half a dozen.

The tree may serve as a receiving station for several sets, either connected in series with the same material or from separate terminals.

Some skeptics have expressed the belief that it was not the tree, but the wire leading to the nail in the tree which was the real aerial. The absurdity of thinking a 40-foot wire could receive the widely differing wave lengths which come through the tree station is obvious, but to set any doubt at rest, the wire to the tree has been hung to the nail by means of an insulator, when the signals immediately cease, only to come in as strong as ever just as soon as the connection is again established.

Just what will the tree do as a transmitting station for radio telegraphic messages has not been determined in the Signal Corps Experimental Laboratory. As those in charge express it, "The fact has been demonstrated, but the matter is still in laboratory stage only. What remains to be done now is to develop the best methods of using the demonstrated fact".

But it has already been shown that the tree can be used in wireless telephony and for short distances it has been shown that two-way telephonic communications is easily established through trees with remarkably low values of transmitting antenna current.

If a tree may be used to send wireless telephonic waves it seems not unreasonable to suppose that it will do so as easily with the telegraphic waves. At present the Signal Corps is at work on apparatus to test the possibilities of the tree as a transmitting station.

Just what this development of the art of radio telegraphy may mean has not yet been worked out. It is the history of most discoveries that their potentialities are hardly dreamed of when they are first made --- for instance the telephone, the electromagnet, the vacuum tube amplifier. But it seems fairly obvious that in war, at least, the tree receiving station opens up great possibilities.

True enough there are few trees which remain intact under shell fire, and doubtless with this possibility in mind the armies of the future (if there be such) will in action consider all trees as dangerous enemy aerial stations. But there will always be trees behind the lines and not all actions will be fought on bare ground. What would it have meant to the "lost battalion" to have had a tree wireless set along by which it could have heard that every effort was being made to find and relieve it, or by which it might have sent back messages supplementing that carried by the pigeon?

The greatest development, however, of the tree as the foundation for a receiving and possibly a sending station will come in peace uses. General Squier has written:

"In view of what has been accomplished in space telegraphy, it is difficult to predict to what extent this means of communication may ultimately be developed. If, as indicated in these experiments, the earth's surface is already generously provided with efficient antennae, which we have but to utilize for such communication, even over short distances, it is a fascinating thought to dwell upon in connection with the future development of the transmission of intelligence.

"Since a transmitting station is a central point for electromagnetc waves sent out in all directions over the surface of the earth, a large class of information, such as meteorological reports, crop reports, and general news items of interest to all, may in time be sent from central points, to be received in many places within the radius of influence of the signal station, and this, too, by the simplest form of apparatus."

The amateur wireless world will unquestionably take an intense interest in the tree radio work. At present, while the government has lifted the ban upon amateur aerials, it has not removed the structures against sending.

The aerial is always the greatest problem for the amateur. Lack of both money and material prevents him from erecting anything very large or of very great capacity. If any lad with a receiving set and some thermionic tubes can hook to a tree and take in any wavelength he can tune to, will not tree radio vastly increase the devotees of this particular variety of indoor sport? The matter is one of some importance, inasmuch as many valuable recruits to the radio world have come from amateur ranks, and many a radio engineer had got his first taste for the fascinating art through a homemade tuning coil and detector, under the attic roof. The greater the amateur wireless world, the quicker the development of the art as a whole.

Explorers, discoverers, engineers in far places, the forest service, the woodsman, all have use for the new development. Moreover the tree as an antenna offers unusual possibilities for the investigation of atmospheric phenomena and for what may be called the physics of botany (or the botany of physics) and perhaps is the road by which the unsolved puzzle of growth may be studied.

Meanwhile, it is a thought not without great power to move the sensitive imagination that every tree, growing everywhere, is a wireless tower and antenna and that, as General Squier says, "It is significant that a tree, possessing utility and natural strength, architectural beauty of design and endurance far superior to artificial structures prepared by man, should be able yet further to minister to his needs".

***Electrical Experimenter* (July 1919), p. 204**

Talking Through The Trees

by

Major-General George O. Squier

(Chief Signal Officer, US Army)

How Transatlantic Radio messages Are Copied Via Tree Antenna

As long ago as 1904, the author conducted some experiments with a view to utilizing growing trees as antennae for radio-telegraphy and discovered the efficacy, in a general way, of using a direct metallic contact to certain trees (principally Eucalyptus) to increase the audibility of radio signals. My attention was first called to this phenomenon during the course of summer maneuvers of the Army at Camp Atascadero, CA, where, due to the prevalence of the dry season of the soil, it was found that the regular Army buzzer telephone and telegraph sets were inoperative with any ordinary ground or earth but became operative when connected to a metallic nail driven in the trunk or roots of a live tree. This incident led the author to pursue the subject experimentally in the autumn of 1904 continuing the experiments to the range of frequencies than employed in radio-telegraphy.

Tree Antennae

In connection with the organization and development of Transatlantic radio reception, which was carried out during the period of the war to provide against the possibility of the interruption of the submarine cable system, the Signal Corps established a chain of special receiving stations in different parts of the United States to copy and record enemy and Allied radio messages from European stations for the information of our Army General Staff.

In the prosecution of this work, directions were given to the Signal Corps Laboratory at Camp Alfred Vail, Little Silver, NJ, and also to the experimental staff in Washington to test the efficiency of growing trees as receiving antenna, in connection with this service, using the vastly superior technique and facilities now represented in the radio Art as compared with the crude apparatus with which the discovery was made in 1904. With a collection of apparatus representing the most advanced state of the radio Art, the problem, as a war measure, was attacked anew and has now reached a point where a very brief outline of some of the physical results obtained should be presented in the interests of the development of the Art in general. Since the phenomena involved embrace a variety of physical problems rather than strictly engineering ones, these data are presented in the hope that our scientists may see in the experiments some points of departure for further research.

It was immediately discovered that with the sensitive amplifiers now in use it was possible to receive signals from the principal European stations by simply laying a small wire netting on the ground beneath the tree and connecting an insulated wire to a nail driven in the tree well within the outline of the tree top. See Figure 1. Messages having been received from England, France, Germany and Italy.

This encouraging first result justified a more careful examination of the phenomena and the most suitable arrangement of circuits for the purpose.

And Now For the Floraphone

The messages carried over this tree telephone and telegram system have been named by the writer. They are to be ‘floragrams’. The tree telephone is to be a ‘floraphone’; the tree telegraph a ‘floragraph’.

The discovery is now announced after experiments covering 15 years, beginning in California and continuing intermittently until the outbreak of the war, when they went forward with vigor as an emergency means of communication. The system was utilized during the war in listening-in on the German radio communication.

The final development took place in a small portable laboratory, purchased from a mail order house, capable of being carried to any place in the woods. A group of soldiers, taking turns at copying messages, assisted the writer in the development of the apparatus.

Without entering into the details of these preliminary experiments here it may be said that one fo the best receiving arrangements is found to be an elevated tree earth-terminal in the upper part of the tree top, and an earth consisting practically of several short pieces of insulated wire, sealed at the outer end, radiating out from a common center, and buried a few inches beneath the surface of the ground in the neighborhood of the tree. See Figure 2.

It was soon found that a tree-antenna could be used efficiently as a multiple radio receiving set over widely different wavelengths, see Figure 3A, receiving either from separate terminals at the same (shown dotted in Figure 3A) or different heights of the tree, or in series from the same terminal. See Figure 3B.

This same type of circuit was employed in an inverse manner for radio-telephonic transmitting purposes, although the experiments thus far have been limited to short distances. It was found that 2-way radio-telephonic communication was easily established with remarkably low values of transmitting antenna current. See diagram of this test illustrated at Figure 4.

The flexibility of this arrangement is very striking. The linking up of wire and wireless methods was found to be both convenient and efficient. Radio-telephonic messages from airplanes were readily received by the tree-antenna arrangement and transferred thence to the wire system of the city of Washington and finally received at any point desired.

Furthermore, radio-telephonic transmission through the tree-antenna was received by another tree-antenna, and automatically returned to the sender on a wire system, thus making a complete circuit. Illustrated at Figure 6.

Long distance reception on any wave length from all the larger European stations and from our ships at sea was easily accomplished and traffic copied on a 24 hour schedule by the regular enlisted operators of the Signal Corps. A small portable house serving as a field laboratory was erected in the midst of the forest area on Grant Road, Washington DC, and here was assembled a collection of amplifiers from the Army, navy, the British and French, and American manufacturers. With these facilities it was a matter of a few days to test out, at least in a superficial manner, a large number of proposed arrangements using trees as antenna.

Figure 7 shows how a number of trees can be connected up to give the effect of one large antenna.

In France officers of the Signal Corps, by the simple device of driving a spike into a tree-trunk to which connect the audion set which wireless operators use to make up wireless messages, it was found possible to listen in on communications between German airplanes and the German lines. Messages were thus intercepted in spots into which it would have been impossible to transport a field wireless apparatus. See Figure 8.

The Physics of Tree Wireless

We may regard the metallic electrode rigidly driven into the living organism of a tree, as described above, as a potential earth-terminal for the study of the potential distribution on the surface of the earth itself. It has been shown in these experiments that this metallic terminal intimately connected to the earth itself and a part thereof is subject to changes of potential representing the innumerable frequencies required by modern radio-telephony and telegraphy, as well as any other electrical disturbances which may occur on the surface of the earth or the atmosphere above the earth.

It has also been shown, as expected, that we can select from this composite one or more of the different frequencies by tuned electrical loop circuits suitably connected to this electrode and study each in turn, at will, just as color screens can select a particular component of white light. We may, indeed, by means of a highly insulated conductor bring this terminal directly to the laboratory and connect it immediately to the modern thermionic tube and amplify almost at will the particular effects we are studying…

We can consider that trees have been pieces of electrical apparatus from their beginning and with their manifold chains of living cells are absorbers, conductors and radiators of the long electromagnetic waves as used in the radio Art.

For our present purpose we may consider, therefore, a growing tree as a higly organized piece of living earth, to be used in the same manner as we now use the earth as a universal conductor for telephony and telegraphy and other electrical purposes…

British Patent Specification # 149,917

Improvements in & Relating to Radio Communication Systems

George O. Squier

This invention relates to radio communication systems. More particularly, the invention relates to radio transmission and reception through the use of living vegetable organisms such as trees, plants, and the like.

As disclosed in the Specification of my prior Letters Patent No. 25,610 (1904), I have discovered heretofore that tall trees and like growing vegetation possessed electrical conductivity of a certain nature adapted for the reception of signaling electromagnetic waves and capable of forming a part of an antenna or serial with the use of a direct earth "ground" or equivalent point of connection with the tree, in the potential node region.

I have recently discovered that living vegetable organisms generally are adapted for transmission and reception of radio or high frequency oscillations, whether damped or undamped, with the use of a suitable counterpoise. I have further discovered that such living organisms are adapted for respectively transmitting or receiving a plurality of separate trains of radio or high frequency oscillations simultaneously, in the communication of either or both telephonic or telegraphic messages.

In such use of an antenna comprising living vegetable organism and a counterpoise, I have discovered that optimum results are obtained upon arranging the point of connection of the transmitting or the receiving set within a certain range of the tree, or other living vegetable organism; for trees indigenous in the temperate zones, I have discovered that such optimum point of connection is in a region approximately two-thirds of the height of the tree above the exposed surface of the earth.

In accordance with my invention for receiving radio trains of telephonic or telegraphic high frequency oscillations, a plurality of receiving sets attuned respectively to any desired frequency, may be connected by the same leading-in wire to the same tree, whereby such tree serves as the common receiving antenna for the respective individual receiving sets; and, similarly, for transmitting radio trains of telephonic or telegraphic high frequency oscillations, a plurality of transmitting sets respectively resonant to any desired frequency may be connected by a common lead-in wire to the same tree serving as the common antenna.

In the more preferred forms of my invention, I have devised suitable means for selective directional reception of radio oscillations of any desired definite frequency, by the use of a coil having the turns of its windings disposed in substantial parallelism and mounted to be rotated in a horizontal plane, whereby the received oscillations are restricted to the direction coincident with or parallel to a plane lying normal to any plane passing through any turn of the windings of the coil.

The counterpoise comprises preferably a suitable extent of conductor in the form of one or more lengths of wire disposed below the surface of the earth and suitable insulated therefrom; it is desirable to arrange a number of individual counterpoises, each extending rectilinearly in different directions to one another and to employ in directional selection the particular counterpoise extending substantially in the selected direction.

Further features and objects of the invention will be more fully understood from the following description and the accompanying drawings, in which:

Figure 1 is a diagrammatic vertical elevation of a preferred form of the invention;

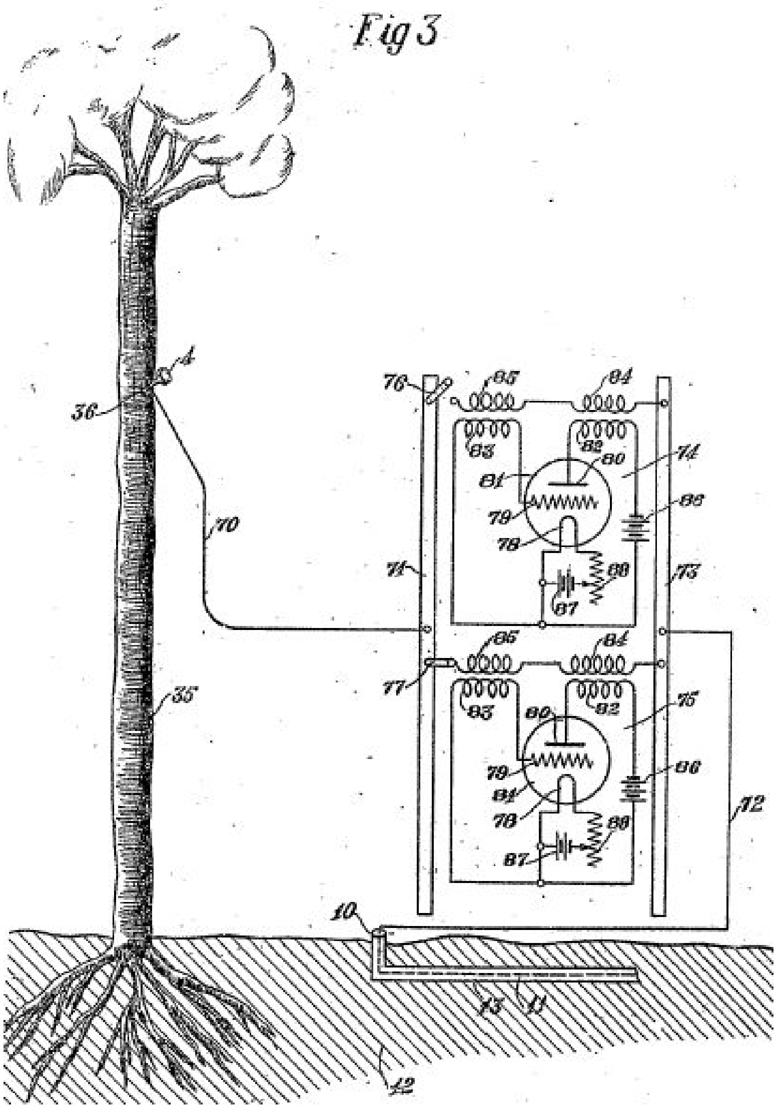
Figure 3 is a diagrammatic view of a preferred form of an arrangement of transmission sets embodying my invention.



Referring to Figure 1, the circuit designated 1 represents any approved form of resonant receiving circuit comprising the variable condenser 2, and detector, rectifier or amplifier 3, arranged with a telephone or any suitable recording device in the usual manner. Such attuned receiving circuit 1 is suitably coupled through transformer windings or otherwise with proper regulatable reactance with the tree or other living vegetable organism and in Figure 1 I have indicated the location 4 as representing the location of a metallic nail, or equivalent, affixed to and extending within the body of such tree. I have discovered that optimum results for any particular tree are dependent upon the physical contour of the space occupied by the branches and leaves as well as the subterranean portions of the tree such as the roots and that generally the optimum results are attained by affixing the nail 4 within the region of the tree substantially two-thirds of the height of the tree above the surface of the earth.

To such nail 4 is connected one end of the lead-in wire 5, preferably enclosed in suitable insulation, and connected at its other end with the resonant circuit 6 comprising the adjustable inductance coil 7 and the adjustable condenser 8. The lead 9 connects the circuit 6 with the counterpoise 10, preferably comprising one or more metallic wires, 11, extending substantially rectilinearly and electrically insulated from the earth 12 by means of suitable insulation 13, as by enclosing such wire or wires 11 within a suitable insulating coating. Such coating 13 extends preferably an appreciable distance above the surface 14 of the earth 12. In the use of my invention with living antennae, I have arranged the counterpoise 10-13 extending in the rectilinear direction substantially parallel to the plane passing through the transmitting station, the receiving station and the center of the earth. It is advantageous to arrange a plurality of individual counterpoises 10 radiating in different rectilinear directions, with a suitable switching device for connecting the lead 9 with the particular counterpoise parallel to or most closely parallel to the selected direction.

Such coil 7 is preferably a primary coil suitably spacially coupled with an adjustable secondary coil 15 connected in the circuit comprising the variable condenser 2 and 3. In the specific form of the invention shown in Figure 1, such secondary coil 15 is provided with the lead wire 16 connected to the terminal 17 of the reversing switch 18 (shown diagrammatically) the other end of the secondary coil 15 being connected by the cross wire 20 of the reversing switch 18. Such terminal 17 is connected by the cross wire 21 with the terminal 24. The pivoted knife blades 25, 26, having the handle 27, are mounted in the usual manner on the central terminals 28, 29. The coil 30 represents diagrammatically a coil comprising a desired number of windings or successive turns of exposed or insulation covered wire, each turn lying substantially in a common vertical plane and the coil indicated at 31 represents a similar plurality of turns of windings mounted in substantially a common vertical plane. One terminal of the coil 30 is connected with one of the central terminals of the reversing switch 18, say terminal 28, and one terminal of the coil 31 is connected with the other central terminal 29, of the reversing switch 18. The other terminal of the coil 30 is connected by the wire 32 with the leads of the variable condenser 2 in shunt with the detector or amplifier 3, while the other terminal of the coil 31 is connected by the wire 33 to the opposite lead of the variable condenser 2 and the detector or amplifier 3.

Such set of coils 30, 31 are suitably mounted to be rotated horizontally, whereby all turns of the coils 30, 31, at any given position lie substantially in a common vertical plane. Such coils 30, 31 may be arranged on a common wooden or like insulating frame of cylindrical, rectangular or other desired contour on cross section.

By virtue of such an arrangement, the primary and secondary circuits are respectively directly exposed to and simultaneously electromagnetically acted upon by the incoming oscillations, and by means of the reversing switch 18 the oscillations generated in the coil 30 may be neutralized or accumulated relatively to the oscillation generated in the coil 31 to produce either the "barrage" or the "amplifying" effect.

By means of such "barrage" effect, the oscillations of any given wavelength directed in any absolute direction are cut out from the detector or amplifying circuit and enable oscillations of similar or the same wave length received in any definite direction to be conducted to the detector or amplifying circuit. By means of such accumulating effect of the coils 30, 31, and the switch 18, the waves of any definite wavelength received in any definite absolute direction are amplified and enable long distance reception at any wave length.

In practice, I have carried out the invention for reception by the use of either a single receiving set or a plurality of receiving sets. Such receiving set or sets may be arranged either to receive damped high frequency oscillations or undamped high frequency oscillations.

In Figure 2 I have illustrated diagrammatically one form of the application of the invention for the simultaneous reception of a plurality of different trains of high frequency oscillations.

The nail 4 is indicated as located in electrical connection with the tree 35 at an optimum point 36, the lead-in wire 37 being connected at its upper end with the nail 4 and at its lower end with the incoming connector bar 38. The connector 38 is provided with the individual switches 39-40-41, etc., corresponding to the number of individual receiving sets. The outgoing connector bar 42 is connected by the lead 43 with the counterpoise 10, preferably constructed and arranged as set forth hereinabove.

In suitable relation with the incoming connector bar 38 and outgoing connector bar 42 and the switches 39, 40, 41 are arranged the respective primary coils 44, 45, 46, etc., respectively coupled in any approved arrangement with the secondary coils 47, 48, 49.

The receiving set 50 is arranged for the reception of undamped waves and is shown of the vacuum tube valve type. The terminals of the secondary 47 are suitably connected in the input circuit including the filament cathode 51 of the vacuum valve 52 and the grid 53 and comprises the variable condenser 54 in shunt with the secondary 47, the condenser 55 and the grid leak resistance 56. The output circuit comprises the battery 58, the filament cathode 51, and the telephone receiver or other audible, or any visual indicator 57. The heating circuit of the filament cathode includes the battery 60 and the variable resistance 61.

The receiving set 62 is shown of a similar undamped oscillation receiving type and like elements are designated by like reference numbers.

The receiving set 63 is indicated of the damped oscillation receiving type and comprises the additional inductance turns 64 having one terminal connected to one terminal of the filament cathode 51 and its other terminal connected to the variable condenser 65 in shunt with the telephone receiver 57 and the storage battery 58. The remaining elements of the receiving set 63 correspond to like elements of the receiving set 50 and are designated by like reference numbers.

In Figure 2 I have shown the switch 39 in closed position with the primary inductance 44 of the receiving set 50, the switch 40 in closed position with the primary inductance 45 of the receiving set 63 and the switch 41 in open position with the primary inductance 46 of the receiving set 62, and accordingly enabling the reception and detection of undamped oscillations of the frequency to which the receiving set 50 is tuned and simultaneously the reception and detection of damped oscillations of the frequency to which the receiving set 53 is tuned.

Figure 3 shows one form of practical application of my invention for transmitting simultaneously radio oscillations, either telephonic or telegraphic, either damped or undamped, or both. The nail 4, lodged at an optimum point 36 in the tree 35, is connected by the lead 70 to the connector bar 71, and the counterpoise 10 is connected by the lead 72 to the connector bar 73.

The transmitting sets 74, 75, etc., of the desired number, are suitably arranged for single or multiple transmission, for which purpose the switches 76, 77, etc., are provided. The transmitting sets 74, 75 are shown of any approved type, such as the oscillating vacuum tube type comprising the filament cathode 78, the grid 79 and anode 80, arranged in the vacuum tube 81, suitably connected with the primary inductance 84, 85. The primary inductances 84, 85 are suitably connected to the connector bar 73 and the connector bar 71 through the respective switches 76, 77. The battery or other source of electric current is indicated at 86. The adjustable heating circuit of the cathode filament 79 is shown comprising the battery 87 and the variable resistance 88.

In Figure 3, the switch 77 is in closed position thus placing the transmitting set 75 in operative connection with the tree serving as the antenna. Upon closing the switch 76 the transmitting set 74 is similarly placed in operative connection with the tree antenna 35. Upon closure of both switches 76, 77 the tree serves as the antenna for the transmission of simultaneous trains of oscillations emitted by the respective transmitting sets 74, 75, modified by a key or telephone transmitter, or other suitable modulator, for the transmission of telegraphic or telephonic messages as desired.

In the use of trees or other living vegetable organisms serving as the antenna or a art thereof, I have discovered from tests that such tree possess impedance consisting of two components, resistance and reactance, the latter being usually condensive, for oscillation within the range of present day wavelengths. The tests also show that the apparent capacity of a tree serving as an antenna is substantially proportional to the height of contact of the lead wire connecting the transmission set with the tree.

The tests also show that the apparent resistance of a tree serving as an antenna is appreciably greater than the resistance of the ordinary metallic antenna, and it is accordingly desirable to modify the resistance or alter the design of the receivers, if it desired to increase the effectiveness of the energy of the electromagnetic radiation impinging on the tree; however, the ordinary receivers of present design may be used and are responsive to any wave length of radiation employed in present day practice.

Whereas I have described my invention by reference to specific forms thereof, it will be understood that many changes and modifications may be made without departing from the spirit of the invention as defined by the appended claims.

An alternative electric power generating system that draws energy from a seemingly unlikely yet abundant, eminently renewable and virtually free power source has been submitted for patenting by MagCap Engineering, LLC, Canton, Mass., in collaboration with Gordon W. Wadle, an inventor from Thomson, Ill. Wadle has invented a way to capture the energy generated by a living non- animal organism --- such as a tree.

Source: KeelyNet / Jerry Decker email (12/21/05)

"Unlimited Electric Energy from the Environment?"

Chris Lagadinos, president of MagCap, developed circuitry that converts this natural energy source into useable DC power capable of sustaining a continuous current to charge and maintain a battery at full charge.

"As unbelievable as it sounds, we've been able to demonstrate the feasibility of generating electricity in this manner," said Wadle.

"While the development is in its infancy, it has the potential to provide an unlimited supply of constant, clean energy without relying on fossil fuels, a power generating plant complex or an elaborate transmission network."

Wadle likened the invention to the discovery of electricity over 200 years ago when charged particles were harnessed to create an electric current. "Now we've learned that there is an immense, inexhaustible source of energy literally all around us that can be harnessed and converted into usable electric power," he said. Ultimately, it should prove to be more practical than solar energy or wind power, and certainly more affordable than fuel cells, he added.

Wadle said he got the original idea of harnessing a tree for electrical energy from studying lightening, more than 50 percent of which originates from the ground. This prompted him to develop the theories resulting in a method to access this power source.

Lagadinos then designed circuitry that filtered and amplified these energy emanations, creating a useable power source.

Basically, the existing system includes a metal rod embedded in the tree, a grounding rod driven into the ground, and the connecting circuitry, which filters and boosts the power output sufficient to charge a battery.

In its current experimental configuration, the demonstration system produces 2.1 volts, enough to continuously maintain a full charge in a nickel cadmium battery attached to an LED light. "Think of the environment as a battery, in this case," said Lagadinos, "with the tree as the positive pole and the grounding rod as the negative."

Lagadinos said the system could be enhanced enough to generate 12 volts and one amp of power, "a desirable power level that could be used to power just about anything," he said. It is enough power to charge batteries for any type of vehicle, including hybrids and electric cars, or to use with an AC converter to produce household power, he added. The LED industry is a prime example of a potential user of this power source.

While the basic concept of this invention -- using a tree to generate electric power -- seems too incredible to be true, Lagadinos said it can be demonstrated quite simply. "Simply drive an aluminum roofing nail through the bark and into the wood of a tree -- any tree -- approximately one half inch; drive a copper water pipe six or seven inches into the ground, then get a standard off-the-shelf digital volt meter and attach one probe to the pipe, the other to the nail and you'll get a reading of anywhere from 0.8 to 1.2 volts of DC power," he said.

"You can't do anything with it in that form because it is 'dirty' -- i.e. highly unstable and too weak to power anything," he added. In order to properly harness this potential energy source, MagCap devised two test circuits: one with three capacitors that were connected in parallel by means of a switch and charged to 0.7 volts each.

When fully charged they are switched to a series mode, multiplying the voltage to 2.1 volts and flashing an LED to show that sufficient power could be generated to produce a useable result. The second circuit included a filtering device to stabilize and "clean" the current so it could be used to charge and maintain a NiCad battery.

The battery then could be connected to the LED to keep the LED lit continuously. Wadle pointed out that there seems to be no limit to the amount of power that can be drawn from an individual tree, no matter how many "taps" are inserted -- each produces the same amount of energy, an average of 0.7 - 0.8 volts. Size of the tree also seems not to matter.

Interestingly, while conventional wisdom would seem to indicate that the tree draws much of its energy from photosynthesis via its leaves, the voltage output actually increases to 1.2-1.3 volts in the winter after the leaves have fallen.

Spray-on antenna: Wireless in a can

by

Amanda Kooser

CHAMTECH
SPRAY ON ANTENNA SYSTEM
DANGER!
NET WT. 10 oz /283 g

Chamtech's spray-on antenna uses a nano material to provide a low-power boost to antenna range. The wireless-in-a-can product may some day bring an end to unsightly cell towers. The antenna can, seen next to a closeup of the nano material.
(Credit: Video screenshot by Amanda Kooser/CNET)

It sounds like a particularly suspicious late-night infomercial: Spray your way to a better wireless signal! Improve your range! Save battery! Transmit over great distances under water!

But Chamtech's spray-on antenna is a real product with some impressive claims. It can be sprayed on almost any surface, even trees and orange barrels. It doesn't suck up power. It works in a mysterious nanotech way.

Here's how I imagine the antenna process goes:

Step 1: Spray antenna material on surface.
Step 2: Connect phone to material.
Step 3: ????
Step 4: Make a phone call to the moon.

Chamtech co-founder Anthony Sutera imagines a world where wireless antenna towers are replaced with nano-paint on walls, and issues like iPhone Antennagate are a thing of the past.

"We have come up with a material that when you spray it on, it lays out just in the right pattern and all of these little capacitors charge and discharge extremely quickly in real time and they don't create any heat," Sutera says in a video presentation about the product.

One of Chamtech's tests turned an RFID chip with a 5-foot range into an RFID chip with a 700-foot range. The company lists a spray antenna kit on its site, but pricing for the public is not revealed. The U.S. government is reportedly already playing with the new material.

If all these claims bear out, then I can see everybody wanting to get their hands on a fresh can full of antenna. My only question is where in the grocery store it will be stocked: with the spray cheese or with the gold food paint?

The amazing spray-on antenna

by

Tyler Holman

Wouldn't it be great if you could just pop out a can of spray-on antenna and boost your signal whenever it was running low? Chamtech Enterprises is hoping to make that dream a reality, and if you happen to work for the government, it already is, according to Chamtech's Solve for X presentation.

Chamtech took to Google's Solve for X to show off the new technology. The company plans to turn its focus towards mobile phones and medical devices, offering a quick solution to boosting signals from existing antennas, or creating new ones. Chamtech's 'antenna in a can' is far more efficient than traditional antenna models, offering energy savings equal to 12 times the amount of energy generated by solar and wind in the US annually - and it even works great underwater.

A traditional antenna would require thousands of watts to send out a signal with a one mile range underwater. Chamtech's can do that with only three watts, and have a stronger signal to boot. So how does all of this work?

The truth is, we don't really know. According to Chamtech's co-founder Anthony Sutera, he and his team came up with it in his living room two years ago. It works by manipulating magnetic and radio signals through mysterious organic materials, and you can spray it on any virtually any surface and hook into it with a flexible circuit cable.

According to Sutera, the US government has had a lot of success with the technology, getting better performance out of it than their existing portable antennas, which he described as some of the best around. With the efficiency and mobility offered, it could even be used to rapidly deploy new infrastructure in disaster areas.

Sutera and chief technology officer Rhett Spencer have coated their car antennas with the stuff, boasting that they can now listen to radio stations in Salt Lake City fifty miles away, with 10,000-foot mountain range in between. Within a few months, they hope to be thinking about financing the company, and are looking at venture capital options to help them bring their technology to you.

For his part, Spencer can't wait. “Can you imagine the infrastructure side of things? Telecomm under the oceans, Internet infrastructure, ships and satellite communications in the sea– they can do it out under the water.” Check out video of Chamtech's Solve for X presentation below.

Chamtech / Sutera Patents

MATERIAL USED FOR AT LEAST ONE OF PROPAGATION, EMISSION AND ABSORPTION OF ELECTROMAGNETIC RADIATION
WO2012078362

Also published as: US2012146855

An antenna system and method for fabricating an antenna are provided. The antenna system includes a substrate (310) and an antenna. The antenna includes a conductive particle based material (320) applied onto the substrate (310). The conductive particle based material (320) includes conductive particles and a binder. When the conductive particle based material (320) is applied to the substrate (310), the conductive particles are dispersed in the binder so that at least a majority of the conductive particles are adjacent to, but do not touch, one another.

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit under 35 U.S.C. $119(e) of a U.S. provisional patent application filed on Nov. 22, 2010 in the U.S. Patent and Trademark Office and assigned Ser. No. 61/416,093, a U.S. provisional patent application filed on Apr. 8, 2011 in the U.S. Patent and Trademark Office and assigned Ser. No. 61/473,726, a U.S. provisional patent application filed on Apr. 20, 2011 in the U.S. Patent and Trademark Office and assigned Ser. No. 61/477,587, and a U.S. provisional patent application filed on Aug. 2, 2011 in the U.S. Patent and Trademark Office and assigned Ser. No. 61/514,435, the entire disclosure of each of which is hereby incorporated by reference.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] The present invention relates to techniques for a material used for at least one of propagation, emission and absorption of electromagnetic radiation. More particularly, the present invention relates to techniques for a conductive particle based material used for at least one of propagation, emission and absorption of electromagnetic radiation.

[0004] 2. Description of the Related Art

[0005] A conventional antenna is a device with an arrangement of one or more conductive elements that are used to generate a radiating electromagnetic field in response to an applied alternating voltage and the associated alternating electric current, or can be placed in an electromagnetic field so that the field will induce an alternating current in the antenna and a voltage between its terminals. The conductive elements employed in the conventional antenna are typically fabricated from solid metallic conductors. However, the use of solid metallic conductors is limiting.

[0006] Therefore, a need exists for an improved material used for at least one of propagation, emission and absorption of electromagnetic radiation, and implementations of the improved material.

SUMMARY OF THE INVENTION

[0007] An aspect of the present invention is to address at least the above-mentioned problems and/or disadvantages and to provide at least the advantages described below. Accordingly, an aspect of the present invention is to provide techniques for a conductive particle based material used for at least one of propagation, emission and absorption of electromagnetic radiation.

[0008] In accordance with an aspect of the present invention, an antenna system is provided. The antenna system includes a substrate and an antenna. The antenna includes a conductive particle based material applied onto the substrate. The conductive particle based material includes conductive particles and a binder. When the conductive particle based material is applied to the substrate, the conductive particles are dispersed in the binder so that at least a majority of the conductive particles are adjacent to, but do not touch, one another.

[0009] In accordance with another aspect of the present invention, an antenna enhancer system is provided. The antenna enhancer system includes an antenna and an antenna enhancer. The antenna enhancer includes a conductive particle based material. The antenna enhancer is disposed adjacent to and offset from the antenna. The conductive particle based material comprises conductive particles and a binder. When the conductive particle based material is disposed adjacent to and offset from the antenna, the conductive particles are dispersed in the binder so that at least a majority of the conductive particles are adjacent to, but do not touch, one another.

[0010] In accordance with yet another aspect of the present invention, a method for fabricating a conformable antenna is provided. The method includes selecting a substrate on which to fabricate an antenna, selecting a template corresponding to an antenna design, the template comprising one or more cut out portions, applying a conductive particle based material, through the one or more cutout portions of the template, and onto the substrate to form the antenna, and fixing a coupler of a feed line to the antenna. The conductive particle based material comprises conductive particles and a binder. When the conductive particle based material is applied to the substrate, the conductive particles are dispersed in the binder so that at least a majority of the conductive particles are adjacent to, but do not touch, one another.

[0011] Other aspects, advantages, and salient features of the invention will become apparent to those skilled in the art from the following detailed description, which, taken in conjunction with the annexed drawings, discloses exemplary embodiments of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0012] The above and other aspects, features, and advantages of certain exemplary embodiments of the present invention will be more apparent from the following description taken in conjunction with the accompanying drawings, in which:

DETAILED DESCRIPTION OF EXEMPLARY EMBODIMENTS

[0023] The following description with reference to the accompanying drawings is provided to assist in a comprehensive understanding of exemplary embodiments of the invention as defined by the claims and their equivalents. It includes various specific details to assist in that understanding but these are to be regarded as merely exemplary. Accordingly, those of ordinary skill in the art will recognize that various changes and modifications of the embodiments described herein can be made without departing from the scope and spirit of the invention. In addition, descriptions of well-known functions and constructions are omitted for clarity and conciseness.

[0024] The terms and words used in the following description and claims are not limited to the bibliographical meanings, but, are merely used by the inventor to enable a clear and consistent understanding of the invention. Accordingly, it should be apparent to those skilled in the art that the following description of exemplary embodiments of the present invention are provided for illustration purpose only and not for the purpose of limiting the invention as defined by the appended claims and their equivalents.

[0025] It is to be understood that the singular forms "a," "an," and "the" include plural referents unless the context clearly dictates otherwise. Thus, for example, reference to "a component surface" includes reference to one or more of such surfaces.

[0026] As used herein, the term "substantially" refers to the complete or nearly complete extent or degree of an action, characteristic, property, state, structure, item, or result. For example, an object that is "substantially" enclosed would mean that the object is either completely enclosed or nearly completely enclosed. The exact allowable degree of deviation from absolute completeness may in some cases depend on the specific context. However, generally speaking the nearness of completion will be so as to have the same overall result as if absolute and total completion were obtained. The use of "substantially" is equally applicable when used in a negative connotation to refer to the complete or near complete lack of an action, characteristic, property, state, structure, item, or result.

[0027] As used herein, the term "about" is used to provide flexibility to a numerical range endpoint by providing that a given value may be "a little above" or "a little below" the endpoint.

[0028] As used herein, the term "antenna" refers to a transducer used to transmit or receive electromagnetic radiation. That is, an antenna converts electromagnetic radiation into electrical signals and vice versa. Electromagnetic radiation is a form of energy that exhibits wave-like behavior as it travels through space. In free space, electromagnetic radiation travels close to the speed of light with very low transmission loss. Electromagnetic radiation is absorbed when propagating through a conducting material. However, when encountering an interface of such a material, the electromagnetic radiation is partially reflected and partially transmitted there-though. Herein, exemplary embodiments of the present invention described below are directed toward techniques that allow for a more efficient interface by reducing the reflections at the interface.

[0029] In addition, exemplary embodiments of the present invention described below relate to techniques for a conductive particle based material used for at least one of propagation, emission and absorption of electromagnetic radiation. While the techniques for the conductive particle based material may be described below in various specific implementations, the present invention is not limited to those specific implementations and is similarly applicable to other implementations.

[0030] An initial overview of the conductive particle based material is provided below and then specific implementations in which the conductive particle based material is employed are described in detail further below. This initial overview of the conductive particle based material is intended to aid readers in understanding the conductive particle based material that is the basis of various exemplary implementations, but is not intended to identify key features or essential features of those various exemplary implementations, nor is it intended to limit the scope of the claimed subject matter.

Conductive Particle Based Material

[0031] In one exemplary embodiment, a conductive particle based material is employed. The conductive particle based material includes at least two constituent components, namely conductive particles and a binder. However, the conductive particle based material may include additional components, such as at least one of graphite, carbon (e.g., carbon black), titanium dioxide, etc.

[0032] The conductive particles may be any conductive material, such as silver, copper, nickel, aluminum, steel, metal alloys, carbon nanotubes, any other conductive material, and any combination thereof. For example, in one exemplary embodiment, the conductive particles are silver coated copper. Alternatively, the conductive particles may be a combination of a conductive material and a non-conductive material. For example, the conductive particles may be ceramic magnetic microspheres coated with a conductive material such as any of the conductive materials described above. Furthermore, the composition of each of the conductive particles may vary from one another.

[0033] The conductive particles may be any shape from a random non-uniform shape to a geometric structure. The conductive particles may all have the same shape or the conductive particles may vary in shape from one another. For example, in one exemplary embodiment, each of the conductive particles may have a random non-uniform shape that varies from conductive particle to conductive particle.

[0034] The conductive particles may range in size from a few nanometers up to a few thousand nanometers. Alternatively, the conductive particles may range in size from about 400 nanometers to 30 micrometers. The conductive particles may be substantially similar in size or may be of various sizes included in the above identified ranges. For example, in one exemplary embodiment, the conductive particles are of various sizes in the range of about 400 nanometers to 30 micrometers. Herein, when a range of sizes of the conductive particles are employed, the distribution of the sizes may be uniform or non-uniform across the range. For example, 75% of the conductive particles may be a larger size within a given range while 25% of the conductive particles are a smaller size.

[0035] An effective amount of conductive particles are included relative to the binder so that the conductive particles are dispersed in the binder. The conductive particles may be randomly or orderly dispersed in the binder. The conductive particles may be dispersed at uniform or non-uniform densities. The conductive particles may be dispersed so that at least a majority of the conductive particles are closely adjacent to, but do not touch, one another.

[0036] The binder is used to substantially fix the conductive particles relative to each other and should be a non-conductive or semi-conductive substance. Any type of conventional or novel binder that meets these criteria may be used. The non-conductive or semi-conductive material of the binder may be chosen to function as a dielectric with a given permittivity.

[0037] The conductive particle based material may be formed as a rigid or semi-rigid structure. For example, the conductive particle based material may be a plastic sheet having the conductive particles dispersed therein. The conductive particle based material may be clear or opaque, and may include any shade of color.

[0038] In addition, the conductive particle based material may be a liquid, paint, gel, ink or paste that dries or cures. Here, the binder may include distillates, hardening agents, or solvents such as a Volatile Organic Compound (VOC). In this case, the conductive particle based material may be applied to a substrate. Also, when the conductive particle based material is a liquid, paint, gel, ink or paste that dries or cures, the binder may adhere to the substrate. The conductive particle based material may be spayed on, brushed on, rolled on, ink-jet printed, silk screened, etc. onto the substrate. The use of the conductive particle based material that is a liquid, paint, gel, ink or paste that dries or cures is advantageous in that the conductive particle based material may be thinly applied to a substrate and conform to the surface of the substrate. This allows the conductive particle based material to occupy very little space and, in effect, blend into the substrate.

[0039] The substrate may be the surface of any conductive, non-conductive or semi-conductive substance. The substrate may be rigid, semi-flexible or flexible. The substrate may be flat, irregularly shaped or geometrically shaped. The substrate may be paper, cloth, plastic, polycarbonate, acrylic, nylon, polyester, rubber, metal such as aluminum, steel and metal alloys, glass, composite materials, fiber reinforced plastics such as fiberglass, polyethylene, polypropylene, fiberglass, textiles, wood, etc.

[0040] The substrate may have a coating applied thereto. The coating may be a conductive, non-conductive or semi-conductive substance. The coating may be a paint, gel, ink, paste, tape, etc. The coating may be chosen to function as a dielectric with a given permittivity.

[0041] At least one of a protective and concealing (or decorative) coating may be applied over the conductive particle based material once it has been applied to a substrate.

[0042] An example of the conductive particle based material is described below with reference to FIG. 1.

[0043] FIG. 1 is a captured image of a conductive particle based material according to an exemplary embodiment of the present invention.

[0044] Referring to FIG. 1, the conductive particle based material includes conductive particles and a binder. The conductive particles are randomly shaped, sized and located. However, conductive particles are dispersed so that at least a majority of the conductive particles are closely adjacent to, but do not touch, one another.

[0045] Herein, without intending to be limiting, for a conductive particle based material of a given density of conductive particles, the conductive particle based material may be applied at a thickness such that the conductive particles are dispersed in the binder so that at least a majority of the conductive particles are closely adjacent to, but do not touch, one another. Herein, without intending to be limiting, it has been observed that a conductive particle based material has a resistance of about 3-17 ohms across any given two points on the surface.

[0046] Herein, without intending to be limiting, it has been observed that when the conductive particle based material is formulated such that the conductive particles are dispersed in the binder so that at least a majority of the conductive particles are closely adjacent to, but do not touch, one another, the conductive particle based material exhibits properties that enable it to at least one of efficiently propagate electromagnetic radiation, efficiently absorb electromagnetic radiation from space, and efficiently emit electromagnetic radiation into space. Moreover, it has been observed that those properties may be either supplemented or enhanced by including an effective amount of carbon, such as carbon black, in the conductive particle based material. For example, an effective amount of carbon black may be an amount that corresponds to about 1-7% of the conductive particles included in the conductive particle based material.

[0047] Without intending to be limiting, it is believed that when electromagnetic radiation is introduced into the conductive particle based material, electromagnetic radiation may pass from conductive particle to conductive particle via at least one of capacitive and inductive coupling. Here, the binder may function as a dielectric. Thus, it is believed that the conductive particle based material may act as an array of capacitors, which may be at least part of the reason why the conductive particle based material at least one of efficiently propagates electromagnetic radiation, efficiently absorbs electromagnetic radiation from space, and efficiently emits electromagnetic radiation into space.

[0048] Alternatively or additionally, and without intending to be limiting, it is believed that the properties that enable the conductive particle based material to at least one of efficiently propagate electromagnetic radiation, efficiently absorb electromagnetic radiation from space, and efficiently emit electromagnetic radiation into space, may be explained by quantum theory at the atomic level.

[0049] Herein, without intending to be limiting, it has been observed that the conductive particle based material generates electrical energy when exposed to sunlight.

[0050] Herein, without intending to be limiting, it has been observed that the resistance of the conductive particle based material continuously changes over time. Herein, without intending to be limiting, it has been observed that, when energized with a radio signal, the conductive particle based material has infinitely low resistance to that signal.

[0051] Herein, while the present disclosure is described in the context of electromagnetic radiation, without intending to be limiting, it is believed that the present invention is equally applicable to bioelectromagnetic energy. Thus, any disclosure herein that refers to electromagnetic radiation equally applies to bioelectromagnetic energy.

Conductive Particle Based Antenna

[0052] In one exemplary embodiment, the conductive particle based material is employed to implement a conductive particle based antenna. When used as a conductive particle based antenna, the conductive particle based antenna is fabricated using the conductive particle based material. Here, the conductive particle based material may be formed into a shape that conforms to the desired characteristics of the antenna. For example, the shape and size of the antenna may vary depending on the frequency and/or polarization of the electromagnetic radiation to be communicated. The conductive particle based antenna is at least one of electrically, capacitively, and inductively coupled to at least one of a receiver, a transmitter, and a transceiver at a coupling point of the conductive particle based antenna. The coupling point of the conductive particle based antenna may substantially be an end point of the conductive particle based antenna. The coupling point of the conductive particle based antenna may be coupled to a coupling point of a feed line electrically connected to the receiver, transmitter, or transceiver. When capacitively or inductively coupled, the coupling may occur through a distance that includes an air gap or that has a substance, such as glass, disposed therein.

[0053] When a conductive particle based antenna is fabricated using the conductive particle based material, the conductive particle based antenna may exhibit a broad bandwidth self-tuning characteristic by using only a small section of the conductive particle based antenna to emit the electromagnetic radiation into space.

[0054] In addition, when the conductive particle based antenna is fabricated using the conductive particle based material, there may be no or little I<2>R losses due the small practical size and the majority of the particles not contacting each other. In addition, there may be no or little Radio Frequency (RF) skin effect losses due to the small practical size. Once the signal is coupled to the conductive particle based antenna, the conductive particle based antenna provides little to no resistance to the transmission signal and it is emitted without significant loss into space. The same may happen in reverse for receiving. That is, the received signal may be absorbed and delivered with little to no loss to the coupling device and is then propagated down a feed line to a receiver.

[0055] An example of the conductive particle based antenna is described below with reference to FIG. 2.

[0056] FIG. 2 illustrates a conductive particle based antenna according to an exemplary embodiment of the present invention. The particular structure of the conductive particle based antenna 200 shown in FIG. 2 is merely an example used for explanation and is not intended to be limiting. The conductive particle based material used to fabricate the conductive particle based antenna 200 of FIG. 2 is assumed to be formulated as a liquid, paint, gel, ink, or paste that dries or cures.

[0057] Referring to FIG. 2, the conductive particle based antenna 200 includes a substrate 210, a first antenna segment 220A, a second antenna segment 220B, a first coupler 230A, a second coupler 230B, and a feed line 240.

[0058] The substrate 210 is a rigid flat sheet of a non-conductive material, such as plexiglass. However, any other surface may be chosen as substrate 210. For example, the surface of a vehicle, the wall of a building, the casing of a wireless device, glass, a tree, cloth, a rock, a plastic sheet, etc., may be chosen as the substrate. When a conductive material is chosen as the substrate 210, an insulative coating of a non-conductive or semi-conductive material may be applied to the area of the substrate 210 where the conductive particle based antenna 200 is to be applied. Examples of the insulative coating of the non-conductive or semi-conductive material include plastic tape, paper tape, paint, etc. Also, when the substrate 210 is a conductive material, the substrate may be utilized as a ground plane. In addition, a surface preparation coating may be applied to the substrate 210 that allows for better adhesion of the conductive particle based material to the substrate 210. The insulative coating may serve the same function as the surface preparation coating. Also, the surface preparation coating may be applied beneath or on top of the insulative coating. Furthermore, the surface preparation coating may be used when the insulative coating in not applied.

[0059] The first antenna segment 220A and the second antenna segment 220B are applied to the substrate 210 according to a desired design. Here, the first antenna segment 220A is functioning as an active antenna element and the second antenna segment 220B is functioning as a ground plane. When the substrate 210 is functioning as a ground plane or an earth ground is employed, the second antenna segment 220B may be omitted. Here, the first antenna segment 220A and the second antenna segment 220B are formed using a conductive particle based material formulated as a liquid, paint, gel, ink, or paste that dries or cures. The non-conductive material may be sprayed on, brushed on, rolled on, silk screened, ink jet printed, etc.

[0060] The first coupler 230A and the second coupler 230B at least one of electrically, capacitively, and inductively couple to the first antenna segment 220A and the second antenna segment 220B, respectively. In addition, the first coupler 230A and the second coupler 230B adhere to, or are otherwise in a fixed relationship with, the first antenna segment 220A and the second antenna segment 220B. The first coupler 230A and the second coupler 230B are electrically connected to respective portions of the feed line 240.

[0061] The feed line 240 is electrically connected to first coupler 230A and the second coupler 230B. Also, the feed line 240 is electrically connected to at least one of a receiver, a transmitter, and a transceiver.

[0062] An example of a structure of a conductive particle based antenna is described below with reference to FIG. 3.

[0063] FIG. 3 illustrates a structure of a conductive particle based antenna according to an exemplary embodiment of the present invention. The particular structure of the conductive particle based antenna shown in FIG. 3 is merely an example used for explanation and is not intended to be limiting. The conductive particle based material used to fabricate the conductive particle based antenna of FIG. 3 is assumed to be formulated as a liquid, paint, gel, ink, or paste that dries or cures.

[0064] Referring to FIG. 3, the conductive particle based antenna includes a substrate 310, first coating 350, conductive particle based material coating 320, and a second coating 360. One or more of the substrate 310, the first coating 350, and the second coating 360 may be omitted. In addition, one or more additional coatings may be utilized.

[0065] The substrate 310 may be any surface of any object, regardless of what material(s) the object is constructed of. For example, the surface of a vehicle, the wall of a building, the casing of a wireless device, glass, a tree, cloth, a rock, a plastic sheet, etc., may be chosen as the substrate. When the substrate 310 is a conductive material, the substrate 310 may function as a ground plane.

[0066] The first coating 350 is applied on top of the substrate 310. The first coating 350 may be at least one of an insulative coating and a surface preparation coating. As an insulative coating, the first coating 350 may be a non-conductive or semi-conductive material. Examples of the insulative coating of the non-conductive or semi-conductive material include plastic tape, paper tape, paint, etc. As a surface preparation coating, the first coating 350 may be any material that allows for better adhesion of the conductive particle based material coating 320 to the substrate 310. The same coating may serve as both the insulative coating and a surface preparation coating. Alternatively, separate insulative and a surface preparation coatings may be utilized either together or individually. The first coating 350 may be formulated as a liquid, paint, gel, ink, or paste that dries or cures. In this case, the first coating 350 may be sprayed on, brushed on, rolled on, silk screened, ink jet printed, etc. The first coating 350 may be omitted.

[0067] The conductive particle based material coating 320 is applied on top of the first coating 350, if present. Otherwise, the conductive particle based material coating 320 is applied on top of the substrate

320. Alternatively, the conductive particle based material coating 320 may be an independent structure. The conductive particle based material coating may be formulated using any formulation of the conductive particle based material described herein. For example, the conductive particle based material coating 320 may be formulated as a liquid, paint, gel, ink, or paste that dries or cures. In this case, the non-conductive material may be sprayed on, brushed on, rolled on, silk screened, ink jet printed, etc.

[0068] The second coating 360, if utilized, is applied on top of the conductive particle based material coating 320. The second coating 360 may serve to protect and/or conceal the conductive particle based material coating 320. The second coating 360 may be any material or structure that protects and/or conceals the conductive particle based material coating 320. The same coating may serve as both the protective coating and the concealment coating. Alternatively, separate protective and concealment coatings may be utilized either together or individually. In one exemplary embodiment, the second coating 360 is formulated as a liquid, paint, gel, ink, or paste that dries or cures. In this case, the second coating 360 may be sprayed on, brushed on, rolled on, silk screened, ink jet printed, etc. The second coating 360 may be omitted.

[0069] Tests were conducted to compare the conductive particle based antenna to a conventional antenna. The conductive particle based antenna was formed using the conductive particle based material whereas the conventional copper antenna was formed using solid copper strips. Both the conductive particle based antenna and the conventional copper antenna were fabricated with the same shape (i.e., the shape shown in FIG. 2) of the same size so that the effect of the particular structure, if any, is equal to both antennas. A non-conductive plexiglass substrate was used to fix both antennas. The same transmit power and frequency were used for the test. The frequency selected was in the range of about 460 MHz. Testing equipment included a Yeasu FT 7900 Dual band FM transceiver, a Telewave Model 44 Wattmeter, and a FieldFox Model N9912A Portable Network Analyzer operated in SA mode used with a Yeasu Model Rubber Duck Antenna that was located 160 feet from the test antennas. The test data for the conventional copper antenna and the conductive particle based antenna are provided below in Table 1.

[0000]

TABLE 1

	Conventional Copper Antenna	**Conductive Particle Based Antenna**
Forward Power	22 watts	41 watts
Reverse Power	12 watts	1 watt
Relative Signal Strength	-35 decibels	-26 decibels

[0070] As can be seen in Table 1, the conductive particle based antenna exhibits a significantly higher forward power (i.e., 41 watts) than the forward power of the conventional copper antenna (i.e., 22 watts). This can be explained by the conductive particle based antenna exhibiting a significantly lower reverse power (i.e., 1 watt) than the reverse power of the conventional copper antenna (i.e., 12 watts). Accordingly, the resulting relative signal strength of the conductive particle based antenna is higher (-26 decibels) than the resulting relative signal strength of the conventional copper antenna (-35 decibels).

[0071] As can be gleaned from the test, for a given antenna structure, the conductive particle based antenna is more efficient at emitting electromagnetic radiation into space than the conventional copper antenna. Therefore, the conductive particle based antenna has a higher effective gain than the conventional copper antenna. Also, since there is less reverse power, less of the electromagnetic radiation input to the conductive particle based antenna may be converted into heat. Thus, the antenna may operate at a lower temperature for a given input power and therefore may have a higher power rating.

[0072] The added gain by using the conductive particle based antenna is well suited to any application in which higher gain and/or lower transmit power for a given antenna structure is desired.

[0073] It has been observed that the transmission performance of the conductive particle based antenna varies depending on the type of amplifier used to drive the antenna. For example, the transmitter used in the Yeasu FT 7900 Dual band FM transceiver in the above test is a class C amplifier. When a linear class A amplifier is employed, the transmission performance of the conductive particle based antenna is reduced and approaches that of the conventional copper antenna. Thus, the performance of the conductive particle based antenna is greater when used with an amplifier that operates for less than the entire input cycle, such as the class C amplifier. While a class C amplifier is referred to herein for convenience in explanation, the use of any amplifier that operates for less than the entire input cycle is equally applicable.

[0074] Herein, power constrained devices typically employ a class C amplifier in order to take advantage of their efficiency so as to conserve power. Similarly, the use of the conductive particle based antenna in power constrained devices that employ a class C amplifier takes advantage of the efficiency of the conductive particle based antenna so as to further conserve power. The power conservation gained by the power constrained devices by using the conductive particle based antenna may allow for longer operational times and/or smaller power source (e.g., batteries) (and thereby smaller devices and/or a lower cost).

Conductive Particle Based Antenna Enhancer

[0075] In one exemplary embodiment, the conductive particle based material is employed to implement a conductive particle based antenna enhancer. When used as a conductive particle based antenna enhancer, the conductive particle based antenna enhancer is fabricated using the conductive particle based material. Here, the conductive particle based antenna enhancer is disposed in an adjacent offset relationship to a conventional antenna with a non-conductive or semi-conductive material disposed there between. Alternatively or additionally, an air gap between the conventional antenna and the conductive particle based antenna enhancer may be employed. Here, the conventional antenna is electrically coupled to at least one of a receiver, a transmitter, and a transceiver.

[0076] In this configuration, the conductive particle based antenna enhancer is at least one of capacitively and inductively coupled to the conventional antenna. Herein, the electromagnetic radiation that is capacitively and inductively coupled from the conventional antenna to the conductive particle based antenna enhancer is efficiently radiated into space by the conductive particle based antenna enhancer.

[0077] The conductive particle based antenna enhancer may be fabricated and positioned so as to be adjacent and offset from the conventional antenna. For example, the conductive particle based antenna enhancer may be added or built into a structure that places it in an adjacent and offset relationship to the conventional antenna.

[0078] For example, the structure may create an air gap between the conventional antenna and a surface onto which the conductive particle based material is applied. The structure may be constructed of a nonconductive material. Alternatively, the structure may be constructed of a conductive material and at least partially coated with a nonconductive material. If the structure is constructed of a conductive material, the conductive particle based material may be applied on top of the nonconductive material coating the structure. Herein, the conductive particle based material may be applied to a side of the structure closest to the conventional antenna or a side of the structure furthest from the conventional antenna. The conductive particle based material may be coated with a layer of the nonconductive material or another material. Examples of the structure include a housing of a device (e.g., a housing of a wireless device), an enclosure placed over the existing antenna, and a case placed over a housing of a device (e.g., a protective cover for a wireless device). The conductive particle based material is at least one of capacitively and inductively coupled to the conventional antenna and thereby increases the performance of the conventional antenna. Here, the thickness the nonconductive material and/or air gap directly affects the performance gain of the conductive particle based antenna enhancer and if the nonconductive thickness and/or air gap is too large, performance may decrease. The thickness of the air gap and/or nonconductive material is very small in relationship to the wavelength of the frequency the conventional antenna is designed for. In a specific example of the exemplary implementation described above, a conventional bumper case for an iPhone, which is manufactured by Apple, may have the conductive particle based material applied to a portion thereof that is adjacent to the antenna of the iPhone (the surface that is concealed when the iPhone is installed therein). Here, the conductive particle based material may have a layer of nonconductive material applied on top.

[0079] Another example of an implementation of a conductive particle based antenna enhancer is described below with reference to FIG. 4.

[0080] FIG. 4 illustrates an implementation of a conductive particle based antenna enhancer according to an exemplary embodiment of the present invention. The particular structure of the conductive particle based antenna shown in FIG. 4 is merely an example used for explanation and is not intended to be limiting. The conductive particle based material used to fabricate the conductive particle based antenna enhancer of FIG. 4 is assumed to be formulated as a liquid, paint, gel, ink, or paste that dries or cures.

[0081] Referring to FIG. 4, a wireless device 480 and a protective cover 490 are shown. The wireless device 480 includes an internal antenna 470. The protective cover 490 includes a conductive particle based antenna enhancer 420 that is disposed so as to be adjacent to the internal antenna 470 when the wireless device 480 is disposed in the protective cover 490.

[0082] While the conductive particle based antenna enhancer 420 is shown to correspond to the size of the internal antenna 470, the conductive particle based antenna enhancer 420 may be smaller or larger than the internal antenna 470. In addition, while the conductive particle based antenna enhancer 420 is shown as being disposed immediately adjacent to the internal antenna, the conductive particle based antenna enhancer 420 may be disposed at a different location on the protective cover 490.

[0083] While the conductive particle based antenna enhancer 420 is shown as being applied to an inner surface of the protective cover 490, the conductive particle based antenna enhancer 420 may be applied to an outer surface of, or may be disposed within, the protective cover 490. When the conductive particle based antenna enhancer 420 is disposed within the protective cover 490, the material used to construct the protective cover 490 may serve as the binder for the conductive particle based material. When, the conductive particle based antenna enhancer 420 is disposed at an inner or outer surface of the conductive particle based material, one or more of an insulative coating, a surface preparation coating, a protective coating, and a concealment coating may be used. In addition, the conductive particle based antenna enhancer 420 may be formed as an independent structure (with or without a substrate) that is fixed to the protective cover 490.

[0084] The conductive particle based antenna enhancer may be added to an existing conventional antenna or may be added at the time the conventional antenna is fabricated.

[0085] In one exemplary embodiment, the conductive particle based antenna enhancer is used to coat a conventional antenna that has been coated with a non-conductive material. The coating of the non-conductive material may be implemented as a liquid, paint, gel, ink, or paste that dries or cures. Herein, the non-conductive material may be sprayed on, brushed on, rolled on, silk screened, ink jet printed, etc. Alternatively, the coating of the non-conductive material may be a film or tape that is applied to the conventional antenna. Layers of other materials may be disposed between the conventional antenna and the non-conductive material and/or between the non-conductive material and the conductive particle based material. Here, depending on the configuration, the conductive particle based material may be coated with a layer of the nonconductive material and/or another material. Here, the thickness the non-conductive material may directly affect the performance gain of the conductive particle based material and if the thickness of the non-conductive material is too large, performance may decrease. The thickness of the non-conductive material is very small in relationship to the wavelength of the frequency the conventional antenna is designed for.

[0086] An example of a structure of a coated conductive particle based antenna enhancer is described below with reference to FIG. 5.

[0087] FIG. 5 illustrates a structure of a coated conductive particle based antenna enhancer according to an exemplary embodiment of the present invention. The particular structure of the conductive particle based antenna shown in FIG. 5 is merely an example used for explanation and is not intended to be limiting. The conductive particle based material used to fabricate the conductive particle based antenna of FIG. 5 is assumed to be formulated as a liquid, paint, gel, ink, or paste that dries or cures.

[0088] Referring to FIG. 5, the coated conductive particle based antenna includes a conventional antenna 570, a first coating 550, a conductive particle based material coating 520, and a second coating 560. One or more of the first coating 550, and a second coating 560 may be omitted. In addition, one or more additional coatings may be utilized.

[0089] The conventional antenna 570 may be any surface of any conventional antenna, which in this example, is assumed to be constructed of a conductive material such as metal.

[0090] The first coating 550 is applied on top of the conventional antenna 570. The first coating 550 may be at least one of an insulative coating and a surface preparation coating. As an insulative coating, the first coating 550 may be a non-conductive or semi-conductive material. Examples of the insulative coating of the non-conductive or semi-conductive material include plastic tape, paper tape, paint, etc. As a surface preparation coating, the first coating 550 may be any material that allows for better adhesion of the conductive particle based material coating 520 to the conventional antenna 570. The same coating may serve as both the insulative coating and a surface preparation coating. Alternatively, separate insulative and a surface preparation coatings may be utilized either together or individually. The first coating 550 may be formulated as a liquid, paint, gel, ink, or paste that dries or cures. In this case, the first coating 550 may be sprayed on, brushed on, rolled on, silk screened, ink jet printed, etc. The first coating 550 may be omitted.

[0091] The conductive particle based material coating 520 is applied on top of the first coating 550, if present. Otherwise, the conductive particle based material coating 320 is applied on top of the conventional antenna 570. The conductive particle based material coating may be formulated using any formulation of the conductive particle based material described herein. For example, the conductive particle based material coating 520 may be formulated as a liquid, paint, gel, ink, or paste that dries or cures. In this case, the non-conductive material may be sprayed on, brushed on, rolled on, silk screened, ink jet printed, etc.

[0092] The second coating 560, if utilized, is applied on top of the conductive particle based material coating 520. The second coating 560 may serve to protect and/or conceal the conductive particle based material coating 520. The second coating 560 may be any material or structure that protects and/or conceals the conductive particle based material coating 520. The same coating may serve as both the protective coating and the concealment coating. Alternatively, separate protective and concealment coatings may be utilized either together or individually. In one exemplary embodiment, the second coating 560 is formulated as a liquid, paint, gel, ink, or paste that dries or cures. In this case, the second coating 560 may be sprayed on, brushed on, rolled on, silk screened, ink jet printed, etc. The second coating 560 may be omitted.

[0093] The conductive particle based antenna enhancer may be fabricated and positioned so as to be adjacent and offset from all or a portion of the conventional antenna. For example, the conductive particle based antenna enhancer may be fabricated and positioned so as to be adjacent to a portion of the conventional antenna corresponding to half or a quarter of the desired wavelength.

[0094] An example of an antenna partially coated with a conductive particle based antenna enhancer is described below with reference to FIG. 6.

[0095] FIG. 6 illustrates an antenna partially coated with a conductive particle based antenna enhancer according to an exemplary embodiment of the present invention. The particular structure of the antenna partially coated with the conductive particle based antenna enhancer shown in FIG. 6 is merely an example used for explanation and is not intended to be limiting. The conductive particle based material used to fabricate the conductive particle based antenna of FIG. 6 is assumed to be formulated as a liquid, paint, gel, ink, or paste that dries or cures.

[0096] Referring to FIG. 6, an antenna 670 that is connected to a feed line 640 is shown. The antenna 670 is partially coated with a conductive particle based antenna enhancer 620. As can be seen, the conductive particle based antenna enhancer 620 coats about a quarter of the antenna 670.

[0097] Tests were conducted to compare a conventional copper antenna to the conventional copper antenna with the conductive particle based antenna enhancer. In particular, the same equipment and testing conditions as the test described above with respect to the conductive particle based antenna were performed. Here, insulative tape was applied to the entirety of the conventional copper antenna and the conductive particle based material was then applied onto the insulative tape.

[0098] The test data for the conventional copper antenna and the conventional copper antenna that has been enhanced with the conductive particle based antenna enhancer are provided below in Table 2.

[0000]

TABLE 2

Conventional Copper Antenna with Conventional Conductive Particle Based Antenna Copper Antenna Enhancer

Forward Power	22 watts	28 watts
Reverse Power	12 watts	10 watts
Relative Signal Strength	-35 decibels	-27 decibels

[0099] As can be seen in Table 2, the conventional copper antenna with the conductive particle based antenna enhancer exhibits a significantly higher forward power (i.e., 28 watts) than the forward power of the conventional copper antenna alone (i.e., 22 watts). This can be explained by the conventional copper antenna with the conductive particle based antenna enhancer exhibiting a significantly lower reverse power (i.e., 10 watts) than the reverse power of the conventional copper antenna alone (i.e., 12 watts). Accordingly, the resulting relative signal strength of the conventional copper antenna with the conductive particle based antenna enhancer is higher (-27 decibels) than the resulting relative signal strength of the conventional copper antenna (-35 decibels).

[0100] As can be gleaned from the above identified test, the conventional copper antenna with the conductive particle based antenna enhancer is more efficient at emitting electromagnetic signals into space than the conventional copper antenna alone. Therefore, the conventional copper antenna with the conductive particle based antenna enhancer has a higher effective gain than the conventional copper antenna alone. Also, since there is less reverse power, less of the electromagnetic radiation input to the conventional copper antenna with the conductive particle based antenna enhancer will be converted into heat. Thus, the conventional copper antenna with the conductive particle based antenna enhancer may operate at a lower temperature for a given input power and therefore may have a higher power rating.

[0101] Accordingly, the conductive particle based material may be used to enhance a conventional antenna.

Conductive Particle Based Transmission Line

[0102] The conductive particle based material may be used to form a conductive particle based transmission line. To implement a conductive particle based transmission line, a transmission line is formed in any of the various ways described herein for forming an object using the conductive particle based material. Herein, at least some of the properties that enable the conductive particle based material to efficiently radiate electromagnetic radiation into space allow the conductive particle based material to efficiently radiate electromagnetic radiation down the transmission line formed using the conductive particle based material. The use of the conductive particle based material as a transmission line is beneficial due to its lower resistance and heat generation.

Conductive Particle Based Electromagnetic Radiation Harvester

[0103] The conductive particle based material may be used as an electromagnetic radiation harvester. The high efficiencies of the conductive particle based material in at least one of propagating and absorbing electromagnetic radiation make it ideally suited for use in collecting electromagnetic radiation. While such collected electromagnetic radiation may be electromagnetic radiation that was transmitted with the intention of being harvested by the electromagnetic radiation harvester, the collected electromagnetic radiation may be background electromagnetic radiation. Herein, the electromagnetic radiation harvester may be coupled to a receiver that collects the energy absorbed by the electromagnetic radiation harvester. The electromagnetic radiation harvester is formed in any of the various ways described herein for forming an object using the conductive particle based material.

Conductive Particle Based Conformable Antenna

[0104] The conductive particle based material may be used to construct a conductive particle based conformable antenna. The benefit of the conductive particle based conformable antenna may be easily appreciated when considered in the context of an exemplary use case, which is described below.

[0105] According to the exemplary use case, the conductive particle based conformable antenna may use used in a military setting. The Special Operations community has a major logistical and safety issue when it comes to communications in the theater. The US Department of Defense (DoD) has rapidly expanded its communications capabilities within the radio spectrum. In the past, two way radios in a variety of form factors where used for conventional Push-To-Talk (PTT) communications. The use of these systems has now evolved into a true "Digital Battlefield" consisting of a multitude of communications platforms. Vast arrays of data networks came into reality. The scope of radios used today varies widely from conventional voice to Satellite, mesh networks, to Unmanned Aerial Vehicles (UAVs) and unattended ground sensors.

[0106] The reason this wide variety of systems is mentioned is to give an understanding of why the conductive particle based conformable antenna may be beneficial to the mission of soldiers. Every RF device utilized by the military operates on a wide range of frequencies and a different type of transmission (Amplitude Modulation (AM), Frequency Modulation (FM), Satcom, Single Side band, etc.).

[0107] However, conventional antenna systems are designed and tuned for a limited range of frequencies and are generally designed to work with only one of the hundreds of types of radio devices on the market. The other major downsides to these conventional antenna systems are the logistics of getting them into battle. They are heavy, bulky, expensive, and difficult to transport. Accordingly, there is a need to address the shortcomings of the conventional antenna systems.

[0108] The conductive particle based conformable antenna addresses the shortcomings of the conventional antenna systems by being operable with any and all of the radios currently deployed and being developed. As opposed to being an antenna of fixed form, the conductive particle based conformable antenna may instead be constructed on an as needed basis.

[0109] For example, the conductive particle based conformable antenna may be constructed on site using the conductive particle based material. In this case, the conductive particle based material is a liquid, paint, gel, ink or paste that dries or cures. Herein, the conductive particle based conformable antenna may be applied to a substrate. In particular, the conductive particle based material may be sprayed on, brushed on, rolled on, silk screened, ink jet printed, etc.

[0110] The conductive particle based conformable antenna may be designed based on typical antenna design, theory, and formulas. The antenna design may be generated in advance or at the time the antenna is needed based on desired characteristics.

[0111] The conductive particle based material is applied to the substrate to form the conductive particle based conformable antenna based on the desired antenna design.

[0112] The substrate may be any surface of any material, such as acrylic, ABS, structural foams, solvent sensitive materials such as polycarbonate and polystyrene, and non-porous surfaces including primed wallboard, wood and clean metals, etc.

[0113] When the substrate is a conducting material, a non-conductive or semi-conductive coating may first be applied to the substrate. In this case, the conducting material may serve as a ground plane. When the substrate is a non-conducting material, a ground plane can be accomplished by using the earth's natural ground. Alternatively, the ground plane can be accomplished by fabricating an independent ground plane.

[0114] Once the antenna is fabricated, a feed line is coupled to the conductive particle based conformable antenna and an RF communications device. The conductive particle based conformable antenna is at least one of electrically, capacitively, and inductively coupled to a coupling point of the feed line. The conductive particle based conformable antenna may be coupled to the coupling point of the feed line at an end point of the conductive particle based conformable antenna. When capacitively or inductively coupled, the coupling may occur through a distance that includes an air gap or a substance, such as glass.

[0115] To fabricate the conductive particle based conformable antenna, a template of the desired antenna design may be used. The template may be a sheet formed of any rigid or semi-rigid material in which the desired design of the antenna is cut out.

[0116] An example of a template used to fabricate a conductive particle based conformable antenna is described below with reference to FIG. 7.

[0117] FIG. 7 illustrates a template used to fabricate a conductive particle based conformable antenna according to an exemplary embodiment of the present invention.

[0118] Referring to FIG. 7, a template 700 is shown. The template 700 may be any material that may be used to form a template or stencil. For example, the template 700 may be a sheet formed of a rigid or semi-rigid material. The cut out of the template 700 may be at least one of a positive and a negative of a desired design of an antenna. The template 700 may be an image displayed on a surface showing where conductive particle based material should or should not be applied. The template 700 may be an image displayed on a display or in a guide book that shows a desired design of an antenna. Herein, the template 700 shown in FIG. 7 corresponds to the antenna design shown in FIG. 2.

[0119] Examples of various cutout designs for the template 700 are found in U.S. Design patent application Ser. No. 29/390,425, filed on Apr. 25, 2011, and entitled "ANTENNA"; U.S. Design patent application Ser. No. 29/390,427, filed on Apr. 25, 2011, and entitled "ANTENNA"; U.S. Design patent application Ser. No. 29/390,432, filed on Apr. 25, 2011, and entitled "ANTENNA"; U.S. Design patent application Ser. No. 29/390,435, filed on Apr. 25, 2011, and entitled "ANTENNA"; U.S. Design patent application Ser. No. 29/390,436, filed on Apr. 25, 2011, and entitled "ANTENNA"; U.S. Design patent application Ser. No. 29/390,438, filed on Apr. 25, 2011, and entitled "ANTENNA"; and U.S. Design patent application Ser. No. 29/390,442, filed on Apr. 25, 2011, and entitled "ANTENNA", the entire disclosure of each of which is hereby incorporated by reference.

[0120] An exemplary method for fabricating a conductive particle based conformable antenna using a template is described below with reference to FIG. 8.

[0121] FIG. 8 illustrates a method for fabricating a conductive particle based conformable antenna using a template according to an exemplary embodiment of the present invention. Herein, the conductive particle based material used to fabricate the conductive particle based conformable antenna is assumed to be formulated as a liquid, paint, gel, ink, or paste that dries or cures.

[0122] Referring to FIG. 8, a template and substrate is chosen in step 800. In step 810, the chosen template may be fixed against the chosen substrate. In step 820, the conductive particle based material may then be applied on the template such that the conductive particle based material passes through at least one cut out portion of the template so as to be applied to the corresponding portion of the substrate. The conductive particle based material may be applied until its particle density reaches a certain threshold. This may be determined by measuring the resistance of the material across the length of the antenna (or antenna segment). Here, the threshold may correspond to a predefined resistance or range of resistances (e.g., 11-15 ohms).

[0123] The template may then be removed leaving the conductive particle based material to dry or cure on the chosen substrate according to the desired design. In step 830, one or more coupling points of a feed line may be affixed to the conductive particle based conformable antenna. Herein, step 830 may be omitted. In addition, additional steps may be included, such as applying at least one of an insulative coating, a surface preparation coating, a protective coating, and a concealment coating. Any or all of this fabrication technique may be automated, as will be described below.

[0124] While a conductive particle based conformable antenna is described herein, any disclosure related to a conductive particle based conformable antenna is equally applicable to a conductive particle based conformable antenna enhancer.

Fabrication Techniques for Conductive Particle Based Conformable Antenna

[0125] In one exemplary embodiment, techniques for constructing a conductive particle based conformable antenna are described. Herein, a computerized device is used to generate a template that is used to construct a conductive particle based conformable antenna.

[0126] The computerized device may be any of a desktop computer, a laptop computer, a netbook, a tablet computer, a Personal Data Assistant (PDA), a Smartphone, a portable media device, a specialized mobile device, etc. The computerized device may include one or more of a display, an input unit, a control unit, a printer, memory, a communications unit, and a projection unit.

[0127] The conductive particle based conformable antenna that is constructed using the template may be formed using the conductive particle based material that is sprayable, rollable or brushable. The conductive particle based material may be applied directly onto any substrate. The conductive particle based conformable antenna, once fabricated onto a surface, may be painted over with a paint in order to conceal the antenna, provide protection to the antenna, or provide the antenna with desired aesthetics.

[0128] According to an exemplary embodiment of the present invention, to create and install an antenna, the computerized device may be used to generate the template. The computerized device may include a graphical user interface that queries a user regarding certain characteristics/criteria or otherwise allows a user to enter certain characteristics/criteria. Based on the input characteristics/criteria, the computerized device generates the template. Herein, the user may input less than all of the characteristics/criteria. In this case, the characteristics/criteria not input by the user may be obtained via a formula, or a local or remote database. In addition, assumed values for the characteristics/criteria not input by the user may be used.

[0129] Examples of the characteristics/criteria include one or more of a substrate on which the antenna will be disposed, frequency of operation, aperture or antenna pattern, whether a space saving design is desired, velocity factor, resonant frequency, Q factor, impedance, gain, polarization, efficiency, bandwidth, heat characteristics, type of amplifier, environment, etc. Further, one or more of the characteristics/criteria may include a number of preset options for a given characteristic/criteria. For example, the options for the substrate on which the antenna will be disposed may include one or more of wood, metal, glass, plastic, etc. For another example, the options for the desired antenna pattern include one or more of an omni-directional antenna pattern, a directional antenna pattern, a circular antenna pattern, a phased array antenna pattern, etc.

[0130] The computerized device may guide a user in inputting at least one of the one or more the characteristics/criteria and may request additional information from the user.

[0131] Based on the input one or more characteristics/criteria, the computerized device determines an antenna pattern using a pattern determination algorithm. The antenna pattern may be a preset antenna pattern or an antenna pattern formed based on an algorithm and the input one or more characteristics/criteria. In addition, the computerized device may determine one or more of a scaling factor of the antenna pattern, dimensions of the antenna pattern or elements of the antenna pattern, grain direction, application notes, etc. Alternatively, or additionally, the characteristics/criteria may not be preset.

[0132] The computerized device may determine more than one antenna pattern and may allow a user to select a desired antenna pattern from among the determined more than one antenna pattern.

[0133] Once the antenna pattern is determined, as well as one or more of the scaling factor of the antenna pattern, dimensions of the antenna pattern or elements of the antenna pattern, grain direction, application notes, etc., a resulting template may be at least one of displayed on the display of the computerized device, projected onto a surface using the projection unit of the computerized device, and printed using one of an external and an integrated printed. When a projection unit is employed, the computerized device may further include a device that adjusts the scale of the projected template based on at least the distance between the projection unit and the surface on which the antenna is to be constructed. Further, when a projection unit is employed, the computerized device may further include a device that adjusts the location of the projected template so that the projected template remains on the same location of the surface regardless of the movement of the computerized device. The template may then be used to construct the antenna.

[0134] Also, the template may correspond to digital data that is stored in a storage device or communicated to another device that applies the antenna material based on the digital data.

[0135] In one exemplary embodiment, the computerized device communicates the input characteristics/criteria to a remote computerized device which determines one or more of the antenna pattern, the scaling factor of the antenna pattern, dimensions of the antenna pattern or elements of the antenna pattern, grain direction, application notes, etc., which is then communicated to the computerized device.

[0136] In one exemplary embodiment, the antenna patterns may be stored remotely from the computerized device and communicated to the computerized device before or after the antenna pattern is determined. The antenna patterns may be communicated to the computerized device in response to a request by the computerized device or another entity.

[0137] An exemplary method for fabricating a conductive particle based conformable antenna using a computerized device is described below with reference to FIG. 9.

[0138] FIG. 9 illustrates a method for fabricating a conductive particle based conformable antenna using a computerized device according to an exemplary embodiment of the present invention.

[0139] Referring to FIG. 9, in step 900, the characteristics/criteria are obtained by the computerized device as described above. In step 910, an antenna pattern is selected by the computerized device based on the obtained characteristics/criteria, as described above. In step 920, a template is generated as described above.

[0140] An example of the computerized device described above is described below with reference to FIG. 10.

[0141] FIG. 10 illustrates a structure of computerized device used for fabricating a conductive particle based conformable antenna according to an exemplary embodiment of the present invention.

[0142] Referring to FIG. 10, the computerized device includes a controller 1010, a display unit 1020, a memory unit 1030, an input unit 1040, a communications unit 1050, a template generator 1060, and an antenna generator 1070. One or more of the components of the computerized device shown in FIG. 10 may be omitted. Also, the functions of one or more of the components of the computerized device shown in FIG. 10 may be performed by a combined component. In addition, additional components may be included with the computerized device.

[0143] The controller 1010 controls the overall operations of the computerized device. More specifically, the controller 1010 controls and/or communicates with the display unit 1020, the memory unit 1030, the input unit 1040, the communications unit 1050, the template generator 1060, and the antenna generator 1070. The controller 1010 executes code to have performed or perform any of the functions/operations/algorithms/roles explicitly or implicitly described herein as being performed by a computerized device. The term "code" may be used herein to represent one or more of executable instructions, operand data, configuration parameters, and other information stored in the memory unit 1030.

[0144] The display unit 1020 is used to display information to a user. The display unit 1020 may be any type of display unit. The display unit 1020 may be integrated with or separate from the computerized device. The display unit 1020 may be integrated with the input unit 1040 to form a touch screen display. The display unit 1020 performs any of the functions/operations/roles explicitly or implicitly described herein as being performed by a display.

[0145] The memory unit 1030 may store code that is processed by the controller 1010 to execute any of the functions/operations/algorithms/roles explicitly or implicitly described herein as being performed by a computerized device. In addition, one or more of other executable instructions, operand data, configuration parameters, and other information may be stored in the memory unit 1030. Depending on the exact configuration of the computerized device, the memory unit 1030 may be volatile memory (such as Random Access Memory (RAM)), non-volatile memory (e.g., Read Only Memory (ROM), flash memory, etc.) or some combination thereof.

[0146] The input unit 1040 is used to enable a user to input information. The input unit 1020 may be any type or combination of input unit, such as a touch screen, keypad, mouse, voice recognition, etc.

[0147] The communications unit 1050 transmits and receives data between one or more entities. The communications unit 1050 may include any number of transceivers, receivers, and transmitters of any number of types, such as wired, wireless, etc.

[0148] The template generator 1060 may perform any of the functions/operations/algorithms/roles explicitly or implicitly described herein as being performed when generating a template. For example, the template generator 1060 may be a printer, a cutter, a projector, a display, etc.

[0149] The antenna generator 1070 may perform any of the functions/operations/algorithms/roles explicitly or implicitly described herein as being performed when generating an antenna. For example, the template generator 1060 may be a sprayer that sprays the conductive particle based material onto a substrate.

[0150] Herein, the functionality described above of the computerized device may result from an application installed on and being executed by the computerized device.

[0151] At this point it should be noted that the present exemplary embodiment as described above typically involve the processing of input data and the generation of output data to some extent. This input data processing and output data generation may be implemented in hardware, or software in combination with hardware. For example, specific electronic components may be employed in a mobile device or similar or related circuitry for implementing the functions associated with the exemplary embodiments of the present invention as described above. Alternatively, one or more processors operating in accordance with stored instructions (i.e., code) may implement the functions associated with the exemplary embodiments of the present invention as described above. If such is the case, it is within the scope of the present disclosure that such instructions may be stored on one or more non-transitory processor readable mediums. Examples of the non-transitory processor readable mediums include ROM, RAM, Compact Disc (CD)-ROMs, magnetic tapes, floppy disks, and optical data storage devices. The non-transitory processor readable mediums can also be distributed over network coupled computer systems so that the instructions are stored and executed in a distributed fashion. Also, functional computer programs, instructions, and instruction segments for accomplishing the present invention can be easily construed by programmers skilled in the art to which the present invention pertains.

[0152] While the invention has been shown and described with reference to certain exemplary embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made therein without departing from the spirit and scope of the invention as defined by the appended claims and their equivalents.

Nano Copper

NANO-COPPER PATENTS

Surface plasmon resonance rectenna and preparation method therefor

CN102544182

The invention provides a surface plasmon resonance rectenna and a preparation method therefor. The surface plasma resonance rectenna adopts a three-layer structure, wherein the lower layer is made from metal Ti; a $TiO2$ nanotube array layer is generated on one surface of the metal Ti in an oxidation manner; a Cu nano particle metal layer is arranged on the surface of the $TiO2$ nanotube array layer through photodeposition; and the micro-surface appearance of the Cu nano particle metal layer is nano particles. In the invention, as photodeposition replaces ultrahigh vacuum electron beam evaporation technology, and inexpensive metal copper Cu replaces precious metal Au to prepare the rectenna adopting the Ti/TiO2NT/Cu structure, the difficult problem that the conventional metal layer can not be used in large-scale industrial production due to high cost in deposition technology, equipment investment and precious metal, and green low-cost development of solar energy technology is facilitated.

Method for preparing copper nanowires and copper nano pointed cones

CN102776469

The invention discloses a method for preparing copper nanowires and copper nano pointed cones. The method comprises the steps of heating a copper substrate in oxygenated atmosphere to form a copper oxide thin film or a copper oxide nanowire thin film, placing the films into a vacuum chamber, performing bombarding by using a argon ion source, and controlling the energy and the time of the ion bombarding to obtain nanowires or copper nano pointed cone arrays. According to the method, no catalyst is used, copper nanowires and copper nano pointed cones, which have different density and sizes are prepared on the substrate conveniently, and the prepared copper nanowires and copper nano pointed arrays can be applied to photoelectric devices such as a display device, a lithium battery, a super capacitor and the like.

Method for preparing ultrafine copper powder for electronic paste

CN102764898

The invention belongs to the field of electronic paste and particularly relates to a method for preparing a ultrafine copper powder for the electronic paste, comprising the step of adding a dispersing agent and a reducing agent into a copper salt aqueous solution to reduce the elemental copper. The method is characterized in that nano-copper particles are added into the copper salt aqueous solution before the dispersing agent and the reducing agent are added, wherein the nano-copper particles have the size of 5-20nm, and the addition amount of the nano-copper particles is 0.3-0.6 per mill of the mass of copper salt in the copper salt aqueous solution. The method is simple in process and flexible to operate. The raw materials are nontoxic, environmentally friendly and suitable for industrial production. The ultrafine copper powder prepared by the adopting the method has uniform and controllable particle size, a narrow distribution range and high purity.

Preparation method of nano porous copper capable of being patterned

CN102766893

The invention discloses a preparation method of nano porous copper capable of being patterned, comprising the following steps: (1), sputtering a Cr-Cu seed layer on a sheet glass, spin coating positive photo-resist, baking the photo-resist, exposing, and developing in turn, so as to pattern the nano porous copper photo-resist; (2), depositing a copper stress buffer layer and a Cu-Zn alloy layer by the electro-deposition technique, to obtain a patterned precursor alloy thin film; and (3), performing de-alloying treatment on the patterned Cu-Zn patterned precursor alloy thin film in an acidic solution, removing the positive photo-resist, finally implementing the patterned nano porous copper so as to obtain a nano porous copper array. The preparation method and the micro-processing technique are compatible; specifically, the nano porous copper arrays with various patterns are obtained by the photo resist patterning technique, the Cu-Zn alloy co-deposition technique, and the de-alloying technique; the preparation method has the advantages of simple process, low cost, easy control, and good compatibility to the micro-processing technique.

Method for preparing nano copper lubricating material by wire electrical explosion method

CN102744414

The invention relates to a method for preparing a nano copper lubricating material by a wire electrical explosion method. On the aspect of preparing the nano lubricating material, the method effectively solves the agglomeration problem in the process of preparing nano metal powder by the existing electrical explosion method and fundamentally eliminates the problems of derivatives and impurities in the process of preparing the nano lubricating material by a chemical method. The method comprises the specific steps of: by a device comprising parts such as a high voltage discharge system, a wire throwing system, a liquid circulating system, a vacuum system, an explosion chamber and the like, after vacuumizing to the pressure of minus 0.1MPa and filling argon to the pressure of 0.1 to 0.2MPa, implementing effective crushing on a copper wire section with the specification of phi 0.2*(35 to 60)mm under a voltage of 7 to 13KV and simultaneously infiltrating the obtained product into lubricating oil; and in the electrical exploding process, directly generating a modified thin film on the surface of nano copper powder so as to form nano lubricating oil.

NANOMETER-SIZED COPPER-BASED CATALYST, PRODUCTION METHOD THEREOF, AND ALCOHOL PRODUCTION METHOD USING THE SAME THROUGH DIRECT HYDROGENATION OF CARBOXYLIC ACID
EP2561928

Also published as: US2013030224 (A1) WO2011132957 (A2) WO2011132957 (A9) WO2011132957 (A3) CN102946994 (A)

Disclosed is a nano-sized Cu based catalyst and a method of preparing the same including dissolving, in an aqueous solution, a first component comprising a Cu precursor, a second component precursor comprising one or more selected from the group consisting of a transition metal, an alkaline earth metal and a Group IIIb metal, and a third component precursor comprising one or more selected from the group consisting of alumina, silica, silica-alumina, magnesia, titania, zirconia and carbon and then performing stirring; precipitating the stirred mixture solution using Na2CO3 and NaOH to form a catalyst precursor precipitate; and washing and filtering the formed catalyst precursor precipitate. Also a method of preparing alcohol is provided, including reacting hydrogen with carboxylic acid including a single acid or an acid mixture of two or more acids derived from a microorganism fermented solution, using the nano-sized Cu based catalyst.

Copper nano powder and preparation method of copper nano powder
CN102601381

The invention discloses copper nano powder and a preparation method of the copper nano powder. The powder is prepared by the following methods: preparing copper salt solution from copper salt, adding a drag reduction agent and an inhibitor into the copper salt solution to prepare copper salt mixing solution and pre-heating the copper salt mixing solution; preparing reducing agent solution, adjusting the pH value of the reducing agent solution, and pre-heating the reducing agent solution; uniformly mixing and agitating the copper salt mixing solution and the reducing agent solution, heating the mixture to the reaction temperature to enable the mixture to react for a certain time so as to obtain nano copper suspension solution; aging the nano copper suspension solution; performing vacuum filtration on the suspension solution obtained from the above steps to obtain the copper nano powder in which the impurity is not removed; processing the copper nano powder to obtain the copper nano powder cladded by organic solvent; performing vacuum filtration on the copper nano powder to obtain wet copper nano powder, and performing low-temperature vacuum drying on the copper nano powder obtained from the above steps so as to obtain the copper nano powder product. The powder is small in particle size and narrow in particle size distribution. The method is controllable in reaction process, simple in technology and suitable for industrial production.

Water-soluble nano-copper and preparation method thereof
CN102554217

The invention belongs to the technical field of nanometer materials, and particularly relates to water-soluble nano-copper and a preparation method of the water-soluble nano-copper, wherein the water-soluble nano-copper is nano-copper clusters which are surface-modified by stable organic single molecules formed in a way that organic compound surface modifier containing sulfydryl is bonded on the surface of copper nanoparticles. The invention can obtain copper nanoparticles which can be effectively dispersed in water phases and can exist stably, and is simple in preparation process and preparation devices, low in raw material cost, low in the production cost, high in yield, and suitable for large-scale industrial production, and the raw materials are easily accessible.

New method of preparing powder nano material
CN1436626

The new nano powder material preparing process of the present invention is suitable for preparing carbide, nitride and particle metal powder. The preparing process includes pumping the reactor into vacuum, filling protecting gas or reaction gas, setting graphite electrode inside the reactor, applying voltage between the graphite electrode and the metal inside the crucible inside the reactor to produce high temperature carbon arc and metal vapor. When protecting gas is filled, nano nickel powder, copper powder, aluminum powder and other metal powder coated by graphite atoms with less agglomeration may be prepared. When reaction gas is filled, nano carbide or nitride powder may be prepared. Compared with available technology, the produced nano powder has less agglomeration, the production process has low cost and great arc power and is suitable for large scale production and is widely applicable.

METHOD FOR PREPARING NANO-PARTICLES

EP1550633

Also published as: EP1550633 (A4) EP1550633 (B1) US2004197884 (A1) US7204999 (B2) JP3703479 (B2) more

The method of the production of a nanoparticle of the present invention includes a step of forming a nanoparticle including a compound of a metal ion in a cavity part of a protein, in a solution containing the protein having the cavity part therein, the metal ion, and a carbonate ion and/or a hydrogen carbonate ion. Examples of the aforementioned compound include e.g., a hydroxide. The aforementioned metal ion is preferably any one of a nickel ion (Ni<2+>), a chromium ion (Cr<2+>) or a copper ion (Cu<2+>). According to the aforementioned method, nanoparticles having a uniform particle diameter can be produced.

Method for manufacturing nano-copper

CN1557589

The present invention is nano copper preparing process and belongs to the field of nano material preparing technology in radiochemistry. The technological process includes adopting copper sulfate as copper source, isopropanol as oxidant clearer in water solution, hydrophilic suitable for PVA for controlling the crystal kernel growth speed and grain size and electronic accelerator to produce electron beam for irradiation treatment; washing irradiated solution, centrifugal separation and stoving to obtain claret nano copper powder. The present invention has simple technological process, short production period, no pollution and high safety.

Method for preparing nano copper particle

CN1709617

Also published as: US2006053972 // US7422620

The invention discloses a method for preparation of nm copper grains with very perfect dispersitivity. It comprises copper hydrosol prepared by reduction method, using organic liquor which contains specifical extraction solution to extract copper colloidal granules, and altering polarity of the organic phase to separate nm copper granules. The preparation has very many characteristics, for example, cheap and handy raw material, simplicity and convenience, low cost, high productivity and so on. It fits large-scale industrial production and the diameter of manufactured nm copper granules is between one and ten nm. Also it stabilizes in the air and is able to scatter in the industrial non-polarity organic liquor and kinds of lube. In conclusion, it has extensive industrial purposes.

POWDERS OF NANO CRYSTALLINE COPPER METAL AND NANO CRYSTALLINE COPPER ALLOY...

WO2005092541

A nano crystalline copper metal powder, which comprises aggregates of nano crystal grains of copper metal or a copper alloy, wherein the nano crystal grain has a size of 2 to 1000 nm; a bulk material of a nano crystal copper or copper alloy exhibiting high hardness, high strength, high electric conductivity and high toughness, which comprises a great number of above nano crystal grains being firmly bound with one another; and a method for producing the above bulk material of a nano crystal copper or copper alloy exhibiting high hardness, high strength, high electric conductivity and high toughness, which comprises subjecting the above copper powder or copper alloy powder to a solidification forming such as a vacuum hot solidification forming or an explosive forming, for example, a spark plasma sintering at a temperature of 250 to 700 DEG C, hot pressing, sheath rolling, hot forging, extruding or hot isotropic pressure forming (HIP).

A method and apparatus for the production of copper nanofluids by using chemical method
TWI262111
A method for the production of copper nanofluids uses chemical reduction method. For synthesis of nanofluids containing Cu nanoparticles, copper precursor and reactants (e.g. reducing agent) are mixed uniformly. By controlling the reaction rate and environment, copper particle in nano scale is obtained through nucleation and growth process. The copper nanoparticle can increase the thermal conductivity of nanofluids with its higher thermal conductivity compared with that of fluids.

Preparation of nano copper fluid
CN101264525
The invention relates to a preparation process, belonging to the technical field of the preparation processes for inorganic materials, which comprises the following steps: metallic copper salt and polyethylene pyrrolidone are dissolved into ethylene glycol to form settled solution, then reducing agent is added into the solution and mixed evenly; the mixed liquor is put into a microwave stove for heating and reaction, after cooling, Cu/ ethylene glycol nanometer fluid is obtained. Therefore, the preparation process has the advantages of simple process, low cost, high yield, and facility for industrial production; moreover, the product acquired by use of the preparation process has the advantages of good dispersibility, long-term stability with a plurality of better performances than prior products, and wide popularization and application prospects.

Production of nano-catalyst
CN101028600
A process for preparing the nano-catalyst used to selectively adsorb and convert harmful substances includes such steps as adding copper sulfate and manganese sulfate to deionized water, heating to 80-90 deg.C, stirring, adding strong alkali solution, stirring, filtering, washing the filtered cake until it becomes neutral, drying, calcining, cooling and sieving.

ELECTRODE, AND APPARATUS AND METHOD FOR MANUFACTURING METALLIC FINE PARTICLE
JP2007270184
PROBLEM TO BE SOLVED: To provide a method for manufacturing copper nano particles by which granular nano sized metal fine particles are efficiently manufactured without growing a reduced metal like dendrite (tree branch) and without enlarging the particle size in the mass production of the particles. ; SOLUTION: In the method of manufacturing the copper nano particles, the copper nano particles are manufactured by applying current between an anode comprising copper and a cathode comprising aggregate of many acicular projections of platinum and electrically insulated from the anode. The platinum acicular projections are, for example, cylindrical platinum having <=1 [mu]m diameter or rectangular platinum having <=1 [mu]m one side length and electrolytically deposited on a conductive electrode.

Method for preparing nano copper powder and copper slurry
CN101077529
The present invention is process of preparing nanometer copper powder and copper slurry with high antioxidant performance. The process includes solvent replacement, the first reduction, the second reduction, separation, drying and other steps. The present invention has the features of simple preparation process at normal temperature and normal pressure, low production cost, the effective protection of produced nanometer copper particle in organic phase, small copper powder size, environment friendly preparation process, etc. The prepared nanometer copper powder and copper slurry may be applied in producing large scale PCB, conducting ink, multilayer ceramic capacitor, etc.

Method for preparing nano copper powder

CN101372037

The invention discloses a method for preparing copper nanoparticle. The preparation method is as follows: cupric salt is taken as raw materials; hydroborate serves as reducer; reducer aqueous solution is poured into cupric salt aqueous solution which complexes with ammonia and is stirred quickly, when the cupric salt aqueous solution becomes colorless, the copper nanoparticle is prepared. When the stirring is stopped, the copper nanoparticle sinks quickly, the supernatant fluid is dumped. The copper nanoparticle is washed with water repeatedly, stands and is clarified, and the supernatant fluid is dumped. Finally being filtered, the copper nanoparticle with good dispersibility is prepared by being dried in the flow argon atmosphere. The preparation method has simple production technology, is easy to operate. The copper nanoparticle can be produced on a large scale; and an appropriate covering layer can be covered on the surface of the copper nanoparticle.

COPPER MICROPARTICLE, METHOD FOR PRODUCTION OF COPPER MICROPARTICLE

WO2008041780

Disclosed is a method for producing a copper microparticle, which comprises: a first reduction step for mixing an unsaturated fatty acid solution containing a copper ion with an aldose (a reducing monosaccharide) solution to form an emulsion; a second reduction step for adding an aqueous ascorbic acid solution to the emulsion; and a copper microparticle separation step. The method can produce a copper microparticle which has an average particle diameter of 100 nm or smaller and whose surface is partly or entirely modified with a carboxyl terminal group derived from the unsaturated fatty acid. The copper microparticle produced by the methodshows high dispersibility in spite of having a nano-order size.

METHOD FOR MANUFACTURING METAL NANO PARTICLE SOLUTION

US2009176875

A method for manufacturing a stabilized metal nano particle solution is disclosed. This method manufactures a metal nano particle solution so as to make a metal substance such as silver, gold, copper, zinc or cobalt into ultra-capsular nano particles. That is to say, this new method is simple and suitable for mass production without requiring any separate reducer putting process at a room temperature while a transition metal nano particle solution is produced. In this method, an alcohol solution including a metal salt solution and a soluble polymer is mixed at a room temperature to make a nano metal particle solution with a particle size of 100 nm or less.

Method for preparing metallic simple substance nano-crystal material

CN101279374

A method for preparing metal single substance nanocrystalline materials is applicable to the preparation of the metal nanocrystalline materials of copper, silver, lead, palladium, tin, antimony and so on. A melted composite alkali metal hydroxide solvent is used for carrying out the chemical reaction synthesis under the atmospheric pressure and the temperature of 100 to 300 DEG C, the used raw materials are soluble inorganic metal salts and zinc powder or iron powder, the cost during the synthesis process is low, various parameters in the reaction process are easy to be monitored and controlled, the environmental pollution is less, the evenness of a reaction system is good, the process is simple and the production is easy to be enlarged; ; furthermore, the obtained metal crystal has good crystallization, clean surface and even size, which is applicable to the research of intrinsic properties and the maximization of the functions of the nanocrystalline materials. The metal single substance nanocrystalline materials of the metal nanocrystalline materials are characterized by metal properties, electric and electronic properties, magnetic properties, chemical properties, thermal properties and luminous properties etc., which can be widely used in superconductive, chemical, medical, optical, electronic, electric appliance and other industries.

Surface finish nano copper/copper alloy particles and preparation thereof

CN101259531

The invention relates to a nano-copper/copper alloy particle for surface modification, which is prepared by the following method that: water solution of copper salt or copper salt and alloy component salt with the concentration of 0.001 to 1 mol/L is prepared, then the water solution is fully mixed with the mixed solution of a reductant, a surface modifier and a weak polar or non-polar organic solvent, the still placement is carried out for 30 to 180min after the reaction for 30 to 180min under the alkaline environment with pH of 8 to 13, the organic phase is obtained by separation, and the nano-copper/copper alloy particle for surface modification is obtained after the concentration.; The copper/copper alloy nanoparticle for surface modification which is provided by the invention has controllable particle size and distribution, difficult clustering, good antioxidant property, monodisperse property and good dispersion stability in the organic solvent. The preparation process and a device of the nano-copper/copper alloy particle for surface modification are simple, the raw materials are cheap and easy to obtain, the cost is low, and the yield is high, thus being applicable to the large-scale industrial production.

Method for preparing metallic copper nano particle
CN101337277

The invention relates to a method for preparing metallic copper nanoparticles, and belongs to the technical field of preparing nanomaterial by liquid-phase chemical reduction. The method adopts sodium hydrosulfite as a reducer to reduce cupric hydroxide under alkaline conditions, and adopts sodium dodecyl sulfate as a dispersant to generate copper nanoparticles with the grain diameter of 30 to 90nm. The method has the characteristics of simple technological process, low production cost and suitability for industrialized production.

Preparation method of whole continuous nano-porous copper
CN101596598

The invention relates to a preparation method of whole continuous nano-porous copper, comprising the following steps: (1) heating the pure metallic aluminum and copper to the molten state, stirring and mixing the mixture to form Cu-Al alloy liquid; (2) fast blowing the alloy liquid out with inert gas to solidify the molten liquid metal on the copper rollers which rotate in high speed and prepare alloy strips, or solidify the molten liquid metal in copper molds to prepare alloy plates or alloy bars; and (3) performing dealloying process to the obtained alloy, cleaning the alloy in the distilled water to be neutral and airing the alloy to obtain nano-porous copper. The beneficial effects of the invention are as follows: (1) the produced nano-porous copper is whole continuous and whole continuous nanosize bulk materials can also be prepared; (2) low concentration of corrosion solution is used to prepare nano-porous copper in the method of the invention, and the operation process is simple and the method is suitable for large-scale industrialized production; and (3) according to the components of the mother alloy and the types of corrosion solution, the structure and size of nanoporous copper can be regulated.

Preparation method of nano-copper
CN101607317

The invention belongs to the nanometer material technical field, in particular to a preparation method of nano-copper, comprising the following steps: dissolving copper salt and organic protective agents in a solvent, heating the solution to 30-100 DEG C, simultaneously adding reducing agent in the reaction system to react while stirring for 20-30min, then cooling gradually; standing the cooled solution, and then centrifuging and finally washing the solution with ethanol and acetone repeatedly to obtain pure nano-copper. The invention has simple process, mild reaction conditions and short reaction time; in the reaction process, two protective agents are both adopted to prevent the growth and oxidation of nano-copper; the product performance is good, the particle size of nano-copper is less than 20nm, the nano-copper can not be oxidized for one month in the air; the production cost is low and no hazardous waste can be generated, thus meeting the demand of 'green production'.

PROCEDURE FOR PRODUCTION OF NANO DISPERSED COPPER POWDER
RU2009147519

FIELD: metallurgy. ^ SUBSTANCE: procedure for production of nano dispersed copper powder by reduction consists in mixing copper salt with solution of glucose, in dissolving salt at heating, in introduction of sodium hydroxide, in conditioning under isothermal mode and in successive extraction of metal copper in form of nano dispersed powder. Also, sulphate of copper is used as copper salt. Copper sulphate is mixed with solution of glucose at mole ratio of glucose to copper equal to (1.0-2.5):1.0. Dissolving is carried out at 50-60C. Sodium hydroxide is introduced upon complete copper sulphate dissolving and solution heating to temperature 70C.; It is carried out gradually at several stages for maintaining pH equal to 6-11 in process of reduction reaction, preferably, to 8-9, first to formation of oxide of univalent copper, and further to metal copper. ^ EFFECT: simplified, with reduced prime cost process of production of nano dimension particles of copper due to reduced number of process operations of synthesis.

Method for preparing copper zinc tin sulfur selenium nano particles
CN101830444

The invention relates to a method for preparing copper zinc tin sulfur selenium nano particles, which belongs to the technical field of photoelectric materials. The method comprises the following steps of: 1, mixing divalent zinc salt, divalent tin salt and monovalent or divalent copper salt, adding surfactant into the mixture, and heating the mixture; 2, mixing sulfur powder with selenium powder, adding the surfactant into the mixture, and heating the mixture; and 3, injecting solution obtained by the step 2 into solution obtained by the step 1 for warming, and purifying a product to prepare the copper zinc tin sulfur selenium nano particles. The preparation method has the advantages of no pollution, mild and simple reaction condition and low cost, and is suitable for large-scale production. The forbidden band width of the copper zinc tin sulfur selenium nano particles can change with the proportion change of sulfur selenium.

Method for preparing flaky nano copper powder
CN101890504

The invention discloses a method for preparing flaky nano copper powder, comprising the following steps: compounding a copper salt aqueous solution with a surfactant to obtain a mixed solution A, wherein the water in the copper salt aqueous solution and the surfactant form a surfactant compound system; (2) compounding a reducing agent aqueous solution with the surfactant which is the same as that used in step (1) to obtain a mixed solution B, wherein the water in the reducing agent aqueous solution and the surfactant form the surfactant compound system; (3) mixing the mixed solution B obtained in step (2) and the mixed solution A obtained in step (1) by stirring at the temperature of 20 DEG C to 80 DEG C, and reacting completely with stirring; and (4) carrying out solid and liquid separation on the product, washing the solid, and carrying out vacuum drying to obtain the flaky nano copper powder. The method of the invention has mild condition, simple process, short production period, low equipment investment and low preparation cost, and is easy to realize industrial production. The prepared flaky nano copper powder has consistent appearance, uniform size and good dispersibility.

Method for preparing nano-copper
CN101890506

The invention relates to a method for preparing nano-copper. The method comprises the following steps of: dispersing a copper precursor into the liquid paraffin serving as a solvent and a reducing agent; adding a surfactant into the liquid paraffin with stirring; performing heat treatment for 2 to 4 hours in an atmosphere of N2 protective gas or no protective gas; standing; centrifuging to obtain a product; and alternately washing the product by using petroleum ether, distilled water or absolute ethyl alcohol to obtain the nano-copper. The nano-copper powder prepared by using the method has the advantages of particle sizes of less than 50 nm, uniform distribution, difficult oxidation, high dispersibility in polar solvents or non-polar solvents, cheap raw materials, low energy consumption, simple process equipment and easy large-scale production.

Preparation method of nano-copper powder
CN102586800

The invention discloses a preparation method of nano-copper powder, which comprises the following steps of: in a self-made special electrolytic cell, taking metal copper as an anode, taking conducting material as a cathode, taking electrolyte as organic alcohol, taking ammonium salt which is soluble in the electrolyte as electrolyte, forbidding the ammonium salt to participate chemical reaction, and combining the cathode copper with the organic alcohol, so that the precursor of the nano-copper can be generated; mixing the precursor of the nano-copper, the organic alcohol or the other saturated hydrocarbon with the unsaturated hydrocarbon liquid, and sealing the precursor of the mixed nano-copper in a high-pressure kettle to be subjected to reductive treatment, so that the nano-copper powder can be obtained; and separating the nano-copper powder from the mixture of the reduced nano-copper powder and the organic solvent by an industrial centrifugal machine device, and washing with industrial alcohol, so that wet nano-copper powder can be obtained, putting the nano-copper powder into a vacuum drying oven, and treating, so that the nano-copper powder which accords with the national standard can be obtained. The preparation method has the advantages of being free of pollution in reaction process, small in investment, low in cost, good in product dispersibility, even in distribution, and capable of realizing different-quantity production.

Water-soluble nano-copper and preparation method thereof
CN102554217

The invention belongs to the technical field of nanometer materials, and particularly relates to water-soluble nano-copper and a preparation method of the water-soluble nano-copper, wherein the water-soluble nano-copper is nano-copper clusters which are surface-modified by stable organic single molecules formed in a way that organic compound surface modifier containing sulfydryl is bonded on the surface of copper nanoparticles. The invention can obtain copper nanoparticles which can be effectively dispersed in water phases and can exist stably, and is simple in preparation process and preparation devices, low in raw material cost, low in the production cost, high in yield, and suitable for large-scale industrial production, and the raw materials are easily accessible.

Copper nano powder and preparation method of copper nano powder
CN102601381

The invention discloses copper nano powder and a preparation method of the copper nano powder. The powder is prepared by the following methods: preparing copper salt solution from copper salt, adding a drag reduction agent and an inhibitor into the copper salt solution to prepare copper salt mixing solution and pre-heating the copper salt mixing solution; preparing reducing agent solution, adjusting the pH value of the reducing agent solution, and pre-heating the reducing agent solution; uniformly mixing and agitating the copper salt mixing solution and the reducing agent solution, heating the mixture to the reaction temperature to enable the mixture to react for a certain time so as to obtain nano copper suspension solution; aging the nano copper suspension solution; performing vacuum filtration on the suspension solution obtained from the above steps to obtain the copper nano powder in which the impurity is not removed; processing the copper nano powder to obtain the copper nano powder cladded by organic solvent; performing vacuum filtration on the copper nano powder to obtain wet copper nano powder, and performing low-temperature vacuum drying on the copper nano powder obtained from the above steps so as to obtain the copper nano powder product. The powder is small in particle size and narrow in particle size distribution. The method is controllable in reaction process, simple in technology and suitable for industrial production.

Method for preparing single copper with porous micro/nano hierarchical structure
CN102672198

The invention discloses a method for preparing single copper with a porous micro/nano hierarchical structure. The method comprises the following steps of adding phenol and vitamin C into a mixed culture of copper ion and ammonia water under the condition of one atmosphere at the temperature of 10 to 30 DEG C; quickly reacting; and preparing the single copper with the porous micro/nano hierarchical structure. By adoption of the preparation method, special equipment and reaction conditions are not required, and heating and calcination are not required, or a porous matrix serving as a template is not required to be added. The method has the characteristics that the process is simple, the energy consumption is low, the yield is high and the like, and is environment-friendly and suitable for large-scale industrial production.

Method for preparing ultrafine copper powder for electronic paste
CN102764898
The invention belongs to the field of electronic paste and particularly relates to a method for preparing a ultrafine copper powder for the electronic paste, comprising the step of adding a dispersing agent and a reducing agent into a copper salt aqueous solution to reduce the elemental copper. The method is characterized in that nano-copper particles are added into the copper salt aqueous solution before the dispersing agent and the reducing agent are added, wherein the nano-copper particles have the size of 5-20nm, and the addition amount of the nano-copper particles is 0.3-0.6 per mill of the mass of copper salt in the copper salt aqueous solution. The method is simple in process and flexible to operate. The raw materials are nontoxic, environmentally friendly and suitable for industrial production. The ultrafine copper powder prepared by the adopting the method has uniform and controllable particle size, a narrow distribution range and high purity.

Patented Apr. 4, 1967

3,312,425
AIRCRAFT

Clarence D. Lennon, 1014 12th Ave., St. Petersburg, Fla. 33705, and Robert G. Varner, Box 823, Rte. 1, Palm Harbor, Fla. 33563

Filed Oct. 12, 1965, Ser. No. 495,172
10 Claims. (Cl. 244—12)

This invention relates to aircraft, and more particularly, to aircraft adapted for vertical take-off and landing, an object of which is to effect superior lift characteristics and high lateral speed capability.

Another object is to provide a disc-shaped aircraft including a cabin, a circular, horizontally-disposed, centrifugal impeller assembly around the cabin, and an airfoil embodying a lift and control device mounted circumferentially about, and immediately adjacent to, the impeller assembly, for directing air over and through the airfoil.

Other objects are to provide an airfoil of predetermined shape set at an angle to the horizontal, for effecting optimum lift; to provide an airfoil including a lift and control device having spaced, stationary and movable vanes forming a plurality of air chambers for effecting control, the movable vanes being adjusted to produce directional heading of the aircraft; and to provide an airfoil of the character described having a plurality of orifices selectively opened and closed to produce vertical and lateral thrust components with resultant vertical and lateral movement of the aircraft.

A further object is to provide an aircraft including an impeller assembly and airfoil of the character described, wherein the upper face of the impeller assembly is open and the lower face thereof is normally closed, closure being effected by a system of shutters which are adapted to be opened in the event of failure of the aircraft engines, producing auto-rotation of the impeller, to permit a safe emergency landing.

Other objects of the invention will be manifest from the following description of the present preferred form of the invention, taken in connection with the accompanying drawings, wherein:

FIG. 1 is a front elevational view of an aircraft constructed in accordance with the present invention;

FIG. 2 is a top plan view of the same;

FIG. 3 is a transverse sectional view of the aircraft of the present invention, showing to advantage details of construction;

FIG. 4 is an enlarged sectional view taken along the lines 4—4 of FIG. 3, looking in the direction of the arrows, and showing the movable blade of the impeller assembly forming a part of the present invention;

FIG. 5 is an enlarged sectional view taken on the lines 5—5 of FIG. 3, looking in the direction of the arrows, showing the movable blade of the impeller assembly in inoperative position;

FIG. 6 is a view similar to FIG. 5, showing the movable blade in operative position;

FIG. 7 is a sectional view taken along the lines 7—7 of FIG. 3, looking in the direction of the arrows and showing to advantage the airfoil lift and control assembly forming a part of the present invention;

FIG. 8 is an enlarged horizontal sectional view taken through the airfoil forming a part of the present invention;

FIG. 9 is a sectional view taken on the line 9—9 of FIG. 3, looking in the direction of the arrows, showing to advantage the base of the present aircraft;

FIG. 10 is an enlarged fragmentary plan view of a portion of the base showing to advantage the emergency shutter system forming a part of the present invention;

FIG. 11 is a sectional view taken along the lines 11—11 of FIG. 10, looking in the direction of the arrows, showing in dotted lines, the alternate position of the shutters;

FIG. 12 is a schematic showing of the control system for the movable vanes of the airfoil lift and control device; and

FIG. 13 is a schematic showing of the control mechanism for a sliding valve of the airfoil lift and control assembly forming a part of the present invention.

Referring now in greater detail to the drawings, the aircraft of the present invention comprises a base **20** of disc shape on which is centrally mounted a circular, centrifugal impeller assembly **21**. An airfoil lift and control assembly **22** is mounted circumferentially about, and immediately adjacent impeller assembly **21** for coaction therewith. A cabin **23** is centrally mounted above base **20** and impeller assembly **21**.

As shown to advantage in FIGS. 3 and 9, base **20** includes a central hub **24** from which a plurality of equispaced girders **25** of equal length extend radially. An annular flotation ring **26** is fixed in any suitable manner to the outer limits of girders **25** for buoying the aircraft in water. Base **20** further includes wheel assemblies **27** fixed to, and pending from, flotation ring **26** at 90° intervals for supporting the aircraft on land surfaces.

Base **20** is further provided with a plurality of shutters **28** hingedly connected at **29** to girders **25** intermediate flotation ring **26** and hub **24**. As shown in FIG. 11, shutters **28** are preferably hinged to both faces of each girder **25**, each shutter extending to a point midway adjacent girders **25**, so that a pair of shutters lies between the girders. Each shutter **28** is provided with an extension tab or abutment **30**, the tabs of adjacent shutters **28** being so located that they are contiguous when in the lowered position, as shown in FIG. 10. An inboard slidable ring **31** is supported by girders **25** superjacent extensions **30** of shutters **28**, said ring being provided with a series of recesses or notches **32** normally non-aligned with shutter extension tabs **30** but adapted to be moved into superjacent relationship with the tabs when it is desired to open shutters **28** to the position shown in dotted lines in FIG. 11. Each shutter **28** is additionally provided with an outer extension tab or abutment **33**, which tabs, as shown in FIG. 10, are also adapted to be in contiguous relationship when the shutters are in lowered or closed position. An outboard ring **34** is also slidably supported by girders **25**, which ring is also provided with recesses or notches **35** adapted to register with extensions **33** synchronously with the alignment of inboard ring recesses **32** with extensions **30** to permit opening of the shutters.

In accordance with the objects of the present invention, shutters **28** are opened only in case of emergency to effect safe landing of the aircraft, and the opening is effected manually by means of a shutter cable **36** trained over pulleys **37** and **38** to outboard ring **34**. A supplemental shutter cable **39** affixed to cable **36** is trained over pulley **37** into engagement with movable inboard ring **31**. Cable **36** extends upwardly into cabin **23** for ready access to the pilot. Shutters **28** are normally left in the closed position shown in FIGS. 3 and 9 and are only raised to the open position under emergency conditions to be hereinafter more fully discussed.

Impeller assembly **21** is of the centrifugal type and includes a plurality of vertically-disposed blades **40** extending radially from hub **24** in spaced relationship, a portion of each blade being reduced for interpositioning between base **20** and cabin **23**. The height of each blade **40** is increased laterally of cabin **23** and to the outermost portion thereof is affixed a ring **41** in engagement with the upper edge of each blade and extending completely around the aircraft, for shaping and directing the centrifugal flow of air produced by the rotating blades. Adjacent ring **41**, a portion of blade **40** is hingedly connected at **43** to the main portion thereof to provide a mov-

> Description of incident

(Note: US Patent drawings require an TIFF viewer attachment to Windows Explorer and can be obtained from: Internetiff.com for Explorer & Netscape. The FREE version

works just fine.)

Unable to Date: B1-B,3 CARBURETION, MOORE The most productive in the field of carburetion was George Arlington Moore. Out of 17000 Patents, 250 of them were related to carburetion. As far back as the mid 1920's, Moore was capable of virtually eliminating carbon monoxide pollution with his carburetors. People in the automotive field considered Moore to be a genius and couldn't understand why the automobile industry ignored his inventions. *Want to know more?...*Article Refers to "*"The Works of George Arlington Moore." "* Thanks Christopher Bird. (deceased 1996?) *Want to know more?...*Article US02123485 drawing. (Requires TIFF viewer.)

"Reactionless drive" for airplanes. Said to be "impossible", he demonstrates an easy to build model. *Want to know more?...*Article *Want to know more?...*

END

Jan. 3, 1935 J1-A,1,21 CARBURETION, POGUE, Pat.#353538 (Canadian) Charles N. Pogue is issued a Canadian Patent for a High Mileage Carburetor. (see 1/7/36) (See 1981, Ultra-Lean carburetors)

Apr. 9, 1935 J1-A,1,19 CARBURETION, POGUE, Pat.#US01997497 Charles N. Pogue is issued a Patent for a High Mileage Carburetor. (see 1/7/36) (See 1981, Ultra-Lean carburetors) *Want to know more?...*Article US01997497 drawing.

Jan. 7, 1936 J1-A,1,16 CARBURETION, POGUE, Pat.#US02026798 Charles N. Pogue is issued a Patent for his newer High Mileage Carburetor. Pogue used the carburetor for about ten years on his car and produced about 200 carburetors thru the Economy Carburetor Co. (see 4/30/36;

8/10/36) (See 1981, Ultra-Lean carburetors) *Want to know more?...*Article US02026798 drawing.

early 1936 J1-A,18 CARBURETION, POGUE BREEN MOTOR CO., Winnipeg, Manitoba, Canada: Tests the POGUE Carburetor on a Ford V-8 Coupe and got 26.2 miles on one pint of gasoline. The performance of the car was 100% in every way. Under 10 mph the operation much smoother than a standard carburetor. T.G. Green, President of the BREEN MOTOR CO., did the tests. (see 1/7/36) (See 1981, Ultra-Lean carburetors)

Apr. 30,1936 J1-A,18 CARBURETION, FORD MOTOR CO. FORD MOTOR CO., Winnipeg, Manitoba, Canada: Tests the POGUE Carburetor and is at "a loss to understand" how the carburetor got "25.7 miles on one pint of gasoline"! (That's approximately 205 mpg). Mr. W.J. Holmes and Mr. Purdy conducted the test for FORD MOTOR CO. (see 1/7/36)

Aug. 10,1936 J1-A,18 CARBURETION, POGUE S. Stockhammer tested the POGUE Carburetor on a 1934 Ford V-8 Coupe and got 28 miles per pint of gas. "I can say the performance was all anyone could desire in every shape of form." (see 1/7/36) (See 1981, Ultra-Lean carburetors)

Dec. 12, 1936 J1-A,26 CARBURETION,

POGUE Canadian Automotive Magazine states that the standard carburetor gets about 25 mpg at only 9% efficiency. Therefore the POGUE carburetor is 72% efficient overall at 200 mpg. (see 1/7/36) (See 1981, Ultra-Lean carburetors)

1940 B1-A,37 GENERATOR, FREE ENERGY, MORAY Henry T. Moray demonstrates before members of the Public Utilities Commission (PUC) his FREE ENERGY generator that gave a continuous output of 250,000 volts with no apparent input. The next day he was found shot in his lab and all of his notes and device were stolen. Currently, the Cosray Research Inst. of Salt Lake City has been collecting Moray's papers from old acquaintances and attempting to duplicate the device. (see 1930's)

Oct. 22, 1940 J1-A,14 CARBURETION, NEWBERY, Pat.#US02218922 Ivor B. Newbery gets a Patent for a high mileage carburetor that he says delivers a truly dry vapor to the engine and produces very little, if any, exhaust pollution. *Want to know more?...*Article US02218922 drawing.

1945 Carburetors marked "POGUE CARBURETOR, DO NOT OPEN" were used on unnamed source American Army tanks throughout WWII but were removed from circulation after the war ended. (see 1/7/36)

(See 1981, Ultra-Lean carburetors)

1946 B1-A,40 GENERATOR, FREE ENERGY, COLER, von UNRUH CLASSIFIED BRITISH INTELLIGENCE REPORT: A German researcher by the name of Hans Coler, was visited and interrogated about his "Magneto-tromapparat" FREE ENERGY generator. The inventor claimed to get electrical energy without the use of a chemical or mechanical source of power. This device consisted of only permanent magnets, copper coils, and condensers in a static arrangement and delivered 450mv for a period of some hours. Coler also claimed his "Stromerzouger" could deliver 6kw of power from the few watts delivered by a dry cell. (see also, Joseph Newman). *Want to know more?...*Article "Alleged New Source of Power". Thanks Bob Nelson. mailto:alchemy618@earthlink.net

---

1947 J3-C,43 FLYING SAUCER, T. BROWN Townsend Brown constructed Flying condensers shaped like Saucers. A high positive charge on the leading edge caused thrust to be generated in the direction of the region of low flux density. His Saucers required no jets or propellers, no moving parts at all. They modified the gravity field around themselves to produce, in effect, the incline of a "hill" under the craft, which they slid down like a surfboard on a wave. (aka Biefield-Brown effect) *Want to know more?...*Article "The Flying Saucer" Thanks Mason Rose! Optical Multimedia *Want to know more?...*Article US02949550 1960 Brown flying saucer drawings.

1947 FLYING SAUCER, J.R.R. SEARL. Searl, an military electrical engineer, builds a composite motor driven disc. After starting the device, the force of the disc breaks the motor drive shaft. The disc jumps up into the air, glows blue, and disappears. When the English inventor tries to get a patent on the disc, it is "secretized" by the Queen of England. *Want to know more?...*Article Levitation disc photos. Thanks Bob Nelson! mailto:alchemy618@earthlink.net *Want to know more?...*Article Thanks John Searl!

late 1950's J1-A,1 CARBURETION, FISH/KENDIG B1-B,3 Variable Venturi The Fish/Kendig Variable Venturi carburetors get some very interesting mileage figures. The Fish carburetor even got into production on a small scale, but for some unknown reason, these carburetors fade away in the early 1960's. (see early 1970's) *Want to know more?...*Article US03752451 1973 Kendig variable venturi carburetor drawing. *Want to know more?...*Article US02801086 1957 J. R. Fish carburetor drawing.

1953 J1-A,26 CARBURETION, POGUE CARS Magazine states that in the opening months of 1936, Pogue panicked the Toronto stock exchange and threw fright into the major oil companies. Stock exchange offices & brokers were swamped with orders to dump all oil stock immediately. This same article states that Winnipeg's largest automobile dealers tested the POGUE carburetor and got results of up to 216.8 mpg! (see 1/7/36) (See 1981, Ultra-Lean carburetors)

Mid 1950's B1-B,3 CARBURETION, BASCLE, Pat.#US04257378Joseph Bascle got a Patent for an improved carburetor which was used on every car in the Yellow Cab fleet in Baton Rouge, NY. It raised mileage by 25% and decreased pollution by 45%. *Want to know more?...*Article US04257378 1981 drawing.

1953 J3-E,39 INTEGRATON, VAN TASSEL UFO Contact, George W. Van Tassel begins the construction project on the INTEGRATON machine in Yucca Valley, CA. Its' purpose is to rejuvenate the human physical frame.

(Tom McGraw, deceased, told of sending a camera thru time at the Integratron and photographing dense vegetation of the PAST where, now, is only desert.) *Want to know more?...*Article "Introduction to the Integratron" theintegratron@aol.com

Aug. 23, 1958 J3-A,91 FLYING SAUCER, OTC-X1, CARR Spacecraft Convention, Pleasonton, CA: Panel discussion between Daniel W. Fry and the inventor of the OTC-X1 Flying Saucer, Otis T. Carr and Major Wayne S. Aho, formerly Army Combat Intelligence Officer during WWII. (see 5/5/60)

Mar. 9, 1959 J3-A,49 FLYING SAUCER, OTC-X1, CARR Immediate News Release to ALL Media: OTC Enterprises announces plans to market kit plans to build a prototype model of the firm's projected spacecraft, the OTC-X1, said to be under construction now for launching later this year. Mr. Carr plans to launch a six-foot operating model in April in Oklahoma where it is now being built in field laboratories. (see 4/19/59;5/5/60)

Apr. 19,1959 J3-A,53 FLYING SAUCER, OTC-X1, CARR The OTC-X1 didn't fly for several reason today: Mr. Carr was in the hospital for eight days with lung hemorrhage. There is no indications of cancer, TB or other lung ailments. Also, in the preliminary pre-flight test the accumulator developed a leak which sprayed mercury all over the inside mechanism. "We don't plan to announce the next pre-flight test in advance", said Mr. Wayne S. Aho. (see 5/5/60)

Nov. 10, 1959 J3-A,19 FLYING SAUCER, OTC-X1, CARR Pat.#US02912244Otis T. Carr gets a Patent for an "amusement device" (Flying Saucer). He claims that this actually demonstrates a workable space craft. *Want to know more?...*Article US02912244 drawing.

Dec. 10, 1959 J2-D, J3-A,58 FLYING SAUCER, OTC-X1, CARR Mr. Wayne Aopes to say, "take me to your leader, moon-man!" Mr. Aho announces plans to take the OTC-X1 to the moon at 12:01 a.m. on Dec. 7, 1959. He will get there in 5 hours and orbit it for 7 days, then he will return to earth. The Carr space ship is 45 ft. in diam. and weighs 30 tons and is powered by electricity. Maj. Aho was formerly an Army Intelligence Officer who says he landed on Omaha Beach in Europe on D-Day and won the Bronze Star and Purple Heart for wounds received in the Battle of the Bulge. He claims to have seen 13 Flying Saucers in flight. (see 5/5/60)

May 5, 1960 J3-A,54 FLYING SAUCER, OTC-X1, CARR Pat.#US02912244 Victorville, CA: First time ever in any newspaper: Otis Carr tells how his Flying Saucer, the OTC-X1, works. Carr developed his power plant for the saucer at the Osbrink Plant in Apple Valley.

The OTC- X1 is described "as being two tops that spin in opposite directions around a single axis...The entire circular-foil craft that is Mr. Carr's most profound development, is an assembly of only two major moving mechanical parts." (see 3/9/59;1/61)

*Want to know more?...*Article "Otis T. Carr & his Flying Machine" Thanks Jerry Decker. Jerry Decker

---

June 2, 1960 J3-A,57 FLYING SAUCER, OTC-X1, CARR Otis T. Carr told an "open house" audience of 300 people on Memorial Day that it is a "treacherous misstatement of fact to say or infer that we (OTC Enterprises) are coming to California to raise money in stock sales". Carr appeared to be planning to sell rights to build, sell or operate the OTC-X1 Flying Saucer he claims he'll be producing at the former Osbrink Plant. Thus Carr wouldn't be violating a federal injunction secured by the U.S. Securities Exchange Commission ordering him to stop selling unregistered stock. (see 5/5/60)

Jan., 1961 J2-B,38 FLYING SAUCER, OTC-

X1, CARR True Magazine labels Mr. Otis Carr and his OTC-X1 a hoax and a con-artist. Attorney General J. Lefkowitz is investigating him and Lefkowitz said that Mr. Carr has bilked $50,000 from various people in New York. (see 5/5/60)

1961 B1-A,31 GENERATOR, FREE ENERGY, HENDERSHOT, Dr. Ed Skilling, from Columbia University, successfully builds and test a HENDERSHOT free energy device, out of which he got 300 watts. Skilling had been associated with Hendershot and learned of the device thru him. The generator was self-resonant at 500 khz. (see 1925) *Want to know more?...*Article "Assembly of the Hendershot basket weave Power Capture Unit." Thanks Craig Svenson.

May 2, 1961 J1-A,12 CARBURETION, SHELTON, Pat.#US02982528 Robert S. Shelton gets a Patent for a high mileage carburetor that he claims gives 8 to 10 times the mileage of a standard carburetor. *Want to know more?...*Article US02982528 images.

July 20,1961 J3-A,102 GENERATOR, FREE ENERGY, COLTON IMMEDIATE PRESS RELEASE: I, Norman Evans Colton (Director of Sales, O. T. Carr co.), do hereby declare under oath that I have perfected a machine to draw electricity from the atmosphere without the use of any fuel. The machine is operated entirely by environmental gravitic forces. A newly constructed "Colton-Gravity-Electric-Engine" has been installed at the Claremont Hotel in Berkeley, CA, where it may be seen, examined, evaluated and photographed.

1963 J3-B,51 BINDING METER, W.B. SMITH Wilbert B. Smith, founder and editor of "Topside" magazine, claims to have had contact with Aliens and to have found out the reason why there space ships have crashed. There are certain areas of this planet that are afflicted with "reduced binding". The 3 basic fields of nature that affect "binding" are tempic, electric and magnetic, all of which are non-linear in there reactions to each other. He claims to have developed a "binding meter" to measure these forces. *Want to know more?...*Article Thanks Grant Cameron. presidentialUFO@canada.com

Dec. 26, 1966 J1-A,10 CARBURETION, SCHWARTZ, Pat.#US03294381 Harold Schwartz gets a Patent for a high mileage Vaporizer Carburetor that he claims to be 100% efficient with virtually no exhaust pollution. *Want to know more?...*Article US03294381 drawings.

1966 CANCER CURE, Dr. Wlm. F. Koch, and Dr. F. M. Eugene Blass Confronted by the FDA, both doctors are found murdered in 1966. *Want to know more?...*Article Thanks Mark Lester. email

---

1968 J1-A,1 CARBURETION, FORD MOTOR CO. FORD MOTOR CO. begins experiments with an engine that has a new kind of combustion chamber. A 430 cub. inch is tested and runs very well on a 26:1 air/gas mixture. Estimate possible production by 1985. (see 1985)

Early 1970's B1-B,3 CARBURETION, KENDIG A young college student (name unknown), entered his Mercury "gas hog" in the California Air Pollution car race and won hands down. He was using the KENDIG Variable Venturi carburetor that a small company (name unknown), manufactured in Los Angeles for racing cars. Within a week the student was told to remove the carburetor since it wasn't approved by the Air Resources Board (ARB). His car had reduced pollution and doubled the gas mileage (for that model). (see late 1950's) *Want to know more?...*Article Kendig Technologies, Inc. Thanks Marty!

1970's B1-B,6 ALCOHOL The U.S. Army's Nalick Laboratories in Massachusetts discovered and developed certain fungi which could convert a wide variety of cellulose into the sugars necessary for producing alcohol. Using the fungi to reduce paper scrap, they could produce 65 gals. of high grade alcohol from one ton of scrap. *Want to know more?...*Article DOE 1982 publication #5046267.

1971 ANTI-GRAVITY, Henry Wallace US03626605, US03626606, US03823570Patents awarded to Henry Wm Wallace for "anti-gravity" technology. *Want to know more?...*Article Thanks Robert Stirniman. *Want to know more?...*Article US03626605 diagrams.

1972 J3-E,16 OTEC, NASA NASA Report on OTEC (Ocean Thermal Energy Conversion): "Tapping the energy of the Gulf Stream could supply all the electrical energy needs of the US as far ahead as 1985 with only three-tenths of a degree reduction in the temperature of the great warm ocean river. This reduction may be beneficial as it would slightly offset the ocean's thermal pollution due to other uses." *Want to know more?...*Article What is Ocean Thermal Energy Conversion?

Apr. 4, 1972 J1-A,6 CARBURETION, TUCKER, Pat.#US03653643 Oliver M. Tucker gets a Patent for a high mileage Vaporizer Carburetion System. This is the basic type that La Pan used as mentioned in Mechanics Illustrated. (see 1974) *Want to know more?...*Article US03653643 drawings.

1973 J1-A,1 CARBURETION, SHELL OIL CO. At the Annual SHELL OIL Companies employees contest, a highly modified 1959 Opel sets the record with 376.59 mpg at

Wood River, IL.

1974 B1-B,3 CARBURETION, DRESSERATOR Dresser Company SELLS OUT to Holley Carburetor and FORD MOTOR CO. Lester Berriman spent 5 years designing and testing the "Dresserator" carburetor for Dresser Co. which used a super-accurate mixture control to obtain a 22:1 mixture. Pollution standards were passed along with a typical gain of 18% mpg.

May, 1974 B1-B,6 GAS/WATER ADDITIVE John Andrews, a Portugese chemist, demonstrated a water to gas additive before Navy officials which allowed ordinary water to be added to gasoline without decreasing the combustability of the gas and would drive the cost of gasoline down to 2 cents per gallon. When Navy officials finally went to his lab to negotiate for the formula, they found Andrews missing and his lab ransacked.

Mid 1970's B1-B,3 CARBURETION, FRANCH, KRAFT Guido F. Franch demonstrates a water-to-gas miracle to the chemists at HAVOLINE Chemical Co., MI, and to the University of Michigan. Using a "green powder" starting agent derived from soaking coal in a liquid (unnamed), he cold make water operate a car better than gasoline. He said he learned this process from a coal miner named Alexander Kraft over 50 years before.

1974 J1-A,1 CARBURETION, La Pan An article from Mechanics Illustrated about "Humidifier type fuel systems" tells of a man by the name of La Pan who claims to get from 60 to 100 mpg with his system. Mechanics Illustrated

July, 1974 J3-C,43 GENERATOR, FREE ENERGY, EVGRAY Pat.#3890548 The L.A. District Attorney, acting under orders from the "Top", raids Ed Gray's assembly plant and confiscated his prototype generator as well as his plans and records, brought numerous false charges against him, and defied all attempts by Gray's lawyers to get the confiscated materials returned. Gray's opponents have driven him into bankruptcy. (see 6/17/75)

Apr. 22, 1975 B1-A,26 GENERATOR, FREE ENERGY, ECKLIN, Pat.#3879622 John W. Ecklin, of Alexandria, VA, gets a patent for a FREE ENERGY generator that is powered by 2 kw and delivers 12 kw output.

June 17,1975 B1-A,4-23 ENGINE, FREE ENERGY, EDWIN GRAY, Pat.#3890548 Edwin V. Gray, of Evgray Enterprises, Van Nuys, CA, gets a Patent for a FREE ENERGY automobile engine. The engine starts off of two car batteries and once it gets going, it recharges the batteries and powers the car. Unfortunately, Evgray Ent. has become embroiled in a controversy with the

Securities Exchange Commission (SEC), which is unrelated to the engine itself but has halted the development of the engine. (see 1975)

1975 B1-A,4 ENGINE, FREE ENERGY Governor Ronald Reagan, of California, gave a special commendation to Edwin Gray, of Van Nuys, CA, for his Patent of a FREE ENERGY automobile engine. (see 6/17/75)

Aug. 12, 1975 B1-A,51 GENERATOR, FREE ENERGY, KINNISON, Pat.#US03899703 Robert W. Kinnison of Fort Collins, CO, gets a Patent for a FREE ENERGY generator which offers a hope for a fuelless economy. His design resembles ECKLIN'S generator. (see 4/22/75)

Sep. 18, 1975 J2-F, J3-F,48 Joseph C. Yater invents an Heat-to-Electricity converter that he says will cost the consumer approx. $200 and would be up to 90% efficient. The device operates by capturing "fluctuation voltage" (static noise heard on radios and amplifiers). The rooftop device would be heated by the sun and use millions of microcircuits to tap the freed electrons from heated molecules. Yater took his device to the Government, which declared that his device had "real potential". After being promised a working model within 6 months by the Gov't., they came back to him with the reply that the device would be impractical.

1976 J1-A,1 CARBURETION A modified Ford Pinto equipped with a turbocharged Nissan diesel engine is tested and gets up to 80 mpg.

1977 J1-A,1 CARBURETION Pat.#US04177779 Tom Ogle of El Paso, TX, claims to have gotten 100 mpg on a 1970 Ford Galaxy with a V-8 engine. The Ford used only 2 gals. of gas on a trip from El Paso, TX, to Demming, NM, roundtrip! His Vapor Fuel System eliminates the carburetor and has no exhaust pollution emission! (see 1981) *Want to know more?...*Article US04177779 drawing.

July 26, 1977 J3-D,29 WEATHER CONTROL, CONSTABLE Trevor James Constable aims his Weather Control Machine at the cloud system near Palm Springs, CA, and created a coastal cooling during an excessive heat spell. He also produced record rains for Utah in the worst drought stricken area of the United States. He successfully completed other Weather Divergence plans and notified the Federal Government of these plans as required by Federal Regulations. *Want to know more?...*Article "Loom of the Future, Weather Engineering."

INVENTOR

Walter I. Pennock.

BY

ATTORNEY

UNITED STATES PATENT OFFICE.

WALTER I. PENNOCK, OF PHILADELPHIA, PENNSYLVANIA.

APPARATUS FOR COLLECTING ATMOSPHERIC ELECTRICITY.

No. 911,260. Specification of Letters Patent. Patented Feb. 2, 1909.

Application filed June 26, 1907. Serial No. 380,907.

To all whom it may concern:

Be it known that I, Walter I. Pennock, a citizen of the United States, residing at Philadelphia, in the county of Philadelphia and State of Pennsylvania, have invented certain new and useful Improvements in Apparatus for Collecting Atmospheric Electricity, of which the following is a specification.

My invention relates to a method of collecting electricity from a strata laden with electricity at high altitudes in the atmosphere, through the medium of a wire cable suspended from one or more balloons and in conveying this electricity to the earth's surface.

The object of my invention is to provide a conveyance of the electro motive force to be found in the upper strata of the atmosphere to the earth's surface; where it may be utilized for commercial and other purposes.

A further object of my invention is to provide a device or mechanism by which a suitable collector for the electrical energy in the upper strata of the earth's atmosphere may be elevated in the said strata and by which the said electric energy may be transmitted to and collected at the earth's surface, from which point it may be conducted to any place where it is desired to use the same.

A further object of my invention is to support and anchor said device in any desired position.

A further object of my invention is to provide an improved form of collector through which the energy of the said upper strata of the earth's atmosphere may be collected and transmitted for various purposes to the earth's surface.

Other objects of my invention will appear in the specification and claims below.

For a further full, clear and complete disclosure of my invention, reference may be had to the following description and accompanying drawings, in which like reference characters refer to corresponding parts.

Figure 1 is an elevational view of one form or embodiment of my invention and Fig. 2 is a detailed view of one form of my improved collector.

The passage of the electrical current to the earth under ordinary conditions is prevented by an obstruction afforded by the dense lower strata of the atmosphere, which is a bad conductor of electricity, as shown by the electrodes of an ordinary static machine. When the electrodes are placed close together, the atmosphere is seen to carry the current across from one electrode to another, but if placed far apart the current is obstructed by the intervening air. The dense lower strata of the atmosphere affords one of the best non-conductors of electricity, as shown in the conduction of the electric current by telegraph, or trolley wires on the earth's surface, where only a small quantity of the electric current escapes through the atmosphere; while rarefied atmosphere affords a good conducting media, as shown by the vacuum tube. The upper strata of the atmosphere being rare in proportion to the altitude, and being a good conductor of electricity while the lower strata of the atmosphere being dense and affording a non-conducting media for the electric current, thus causes an obstruction to the electric current, or power in its passage to the earth's surface from the electric strata of the atmosphere under ordinary conditions. When, however, the cumulus clouds of a thunder storm pass over the surface of the earth, these clouds being of very great height, the moisture in said clouds forms a better conductor of electricity than does the dry air, with the result that the electricity in the upper strata of the atmosphere breaks through the said cloud as a streak of lightning and in that form reaches even to the earth's surface, while the thin or shallow strata of clouds, observed in the so-called "settled rain" storm, do not extend upward to a sufficient height to form a conducting medium for the electricity from the electric strata to the earth's surface. For this reason there is usually no lightning during the said latter variety of rain storm.

By means of my invention, I have provided a mechanism for collecting the electrical energy or power created by nature and stored in the upper strata of rarefied air of the earth's atmosphere and have provided a conductor for said electric energy to the earth's surface.

Referring now to the drawings 1 indicates what may be called the lower limits or boundaries of the strata of electric energy above the surface 2 of the earth.

3 indicates a balloon which is elevated to a high altitude until it enters the said stra-

tum. The said balloon 3 carries a bar 4 of wood or any other suitable non-conducting material suspended by insulating links 5 or any other suitable form of insulation from the balloon 3. Upon either end of the said bar 4 I mount collectors, one form of which I have illustrated as spheres of coiled wire 6—6′ the outer ends 7 of which terminate in sharp points. The inner turns of the said spheres 6 and 6′ are wrapped around the wooden bar 4 and united as at 8 to a conductor of electric energy, preferably a large copper wire 9. This wire or conductor 9 extends to the earth's surface and may have its end suitably attached to an electric accumulator or other piece of electrical apparatus. I have illustrated one form of my invention in which the conductor 9 is connected to one pole of a storage battery 10 on the earth's surface.

The spiral spheres 6, 6′ are preferably provided with a polished metallic surface to form a good conductor of electricity and the material of said spheres should also be of such a character that it will not rust or corrode or tarnish. A polished copper wire or a copper wire plated with platinum or gold or a solid platinum or gold wire may be used for this purpose, inasmuch as these materials are least affected by moisture and the atmosphere. The said spheres or collectors may be made of smooth wire as shown in the sphere designated by the numeral 6 or of barbed wire, as is shown at 6′ and illustrated on a larger scale in Fig. 2 of the drawings. The latter form is preferable inasmuch as it provides a large number of points through which the electricity may flow to the wire from the surrounding air in the said upper strata of the earth's atmosphere.

In order that the supporting balloon 3 may be held in a relatively fixed position, it should be suitably anchored to the earth's surface. Inasmuch as the balloon 3 must be elevated to a very high position, the weight of the anchoring cables forms an important consideration, and if desired or necessary one or more supplemental balloons 11, 11, 11 may be attached to each of the anchoring cables 12, 12, 12 as illustrated in Fig. 1, to relieve the balloon 3 of such weight as would prevent it from ascending into the said electrical strata. In order that the electricity from the said upper strata of the earth's atmosphere may not be conducted down the anchoring cables 12, 12, 12, I attach them to the supporting balloon 3 and to the supplemental balloons 11 and to the earth's surface through suitable insulating devices 14.

In the form of my invention illustrated in Fig. 1, below the bar 4, I suspend a ring 13 of any suitable material from the balloon 3, and attach the anchoring cables 12 thereto by means of insulating rings 14, 14, 14. I may also provide additional insulating rings 14 between that portion of the anchoring cables 12 between the balloon 3 and the supplemental balloons 11, and also between that part of the cable 12 between the supplemental balloons 12 and the earth's surface. I may also provide, near the earth's surface and at the lower end of the anchoring cables 12, similar insulating links 14. While I have described links as forming a convenient form of insulating device for the purposes above set forth, I do not wish to be construed as being limited to the same, inasmuch as any suitable non-conducting connection may be used in place of the links 14.

The terminals 15, 15 of the storage battery 10 may be connected to any piece of electric apparatus which it is desired to run or operate and if desirable one of the poles of the battery is adapted to be connected by the switch 16 with the earth's surface. The lower ends of the anchoring cables 12 are securely anchored to the earth's surface as at 17.

With the apparatus arranged and connected in the manner illustrated in Fig. 1, the electric energy in the high strata of the earth's atmosphere passes to and through the conductive spiral spheres 6 or 6′ to the conductor 9 and is suitably stored or used at the earth's surface, while the balloons 11 support a part of the weight of the anchoring cables 12, and permit the balloon 3 to ascend as high as is possible, or necessary for it to enter the said electrical strata of the earth's atmosphere. By arranging the anchorage 17 of the cables 12 symmetrically or in any other position than in a straight line, the balloon 3 may be held in a substantially fixed position with relation to the earth.

While I have illustrated in the drawings and have described in the specification a form of apparatus in which my invention may be carried out, it is obvious that the drawings are more or less diagrammatic drawings, that is to say, that the proportions of the various parts are not necessarily those which would operate to the best advantage, inasmuch as certain portions have been shown as greatly enlarged in the drawings for the sake of clearness, and that it is likely that more than one supplemental balloon would be requird for each cable in order to support the weight of the same, and to relieve the supporting balloon 3 of such weight, as would prevent it from ascending into the high electrical strata of the earth's atmosphere, but such changes in form, proportion and arrangement I regard as being fully within the aim and scope of my invention, so long as such forms or modifications fall within the scope of the appended claims. It is also to be understood that the storage battery or accumulator which I have shown as being connected to my collector, is only a type of apparatus which can be operated by the current collected by the spheres 6, 6′ and transmitted to the earth through the wire 9, and when I use the word "accumulator", I mean any piece of useful apparatus which is operated by the current transmitted thereto through the wire or conductor 9.

Having thus described my invention, what I claim and desire to protect by Letters Patent of the United States is:

1. The combination with an electrical collector comprising a bar of non-conducting material, and an open spherical conductor carried by said bar, of means to support said collector in the high electrical strata of the earth's atmosphere.

2. The combination with a balloon, of an electrical collector supported thereby and insulated therefrom, comprising a bar of non-conducting material, and a conductor wound spirally around said bar.

3. The combination with an electrical collector comprising a non-conducting bar, and a conductive wire wound thereon to form an open substantially spherical body, and means to support said collector in the high electrical strata of the earth's atmosphere.

4. The combination with a balloon, of an electrical collector carried thereby and comprising a non-conducting bar, and a polished wire wound spirally thereon to form an open substantially spherical body.

5. The combination with an electrical collector comprising a non-conducting bar, and a wire wound spirally thereon to form an open substantially spherical body, said wire being provided with pointed conducting projections, and means to support said collector in the high electrical strata of the earth's atmosphere.

6. The combination with a balloon, of an electrical collector carried thereby comprising a non-conducting bar, and a conducting wire wound spirally thereon to form open substantially spherical bodies upon the opposite ends thereof.

7. The combination with a balloon, of an electrical collector carried thereby comprising a non-conducting bar, a conducting wire wound spirally thereon to form open substantially spherical bodies upon the opposite ends thereof, an electrical accumulator, and an electrical connection between the said collector and said accumulator.

8. The combination with a balloon, and means to anchor said balloon, of an electrical collector supported by said balloon and insulated therefrom, an electrical accumulator, and a conductor connecting said collector and said accumulator.

9. The combination of an electrical collector, means to support said collector at a high elevation from the earth's surface and within the electrical strata of the earth's atmosphere, an electrical accumulator at the earth's surface, an electrical connection between said collector and said accumulator, and means to insulate said supporting means from said collector and from the earth.

In testimony whereof, I have hereunto set my hand this 25th day of June, 1907.

WALTER I. PENNOCK.

OVERUNITY ELECTRICITY

Atmospheric Electric Generator

https://overunity-electricity.blogspot.com/2022/04/atmospheric-electric-generator.html?m=0

Atmospheric Electric by Nikola Tesla

Nikola Tesla is known for his invention of the rotating magnetic field, which is the principle behind alternating current (AC) power. He also developed a version of radiant energy he called "Ether Power" or "Atmospheric Electric Generator" (AEG). AEG extracts electrostatic potential from the atmosphere and converts it into useful electrical energy. It is a free-energy device that does not require any external power source to operate.

There are several versions of the AEG design, but all of them extract energy from the atmosphere by using an electrically charged metal plate. The plate is charged by either an external power source or by capturing energy from natural lightning storms. When the plate is exposed to the atmosphere, it creates an electrical field that extracts electrical potential from the air. This potential is then converted into useful electrical energy by one or more electrical generators.

The original version of Nikola Tesla, radiant energy generator, both resonant and non-resonant, can be made in many different versions.

A practical guide to the electrical (non-resonant) calculation of radiant energy: How to Build Tesla's Radiant Energy Receiver

A famous version is Moray's (with resonance to generate arbitrary energy):

Practical guide - in just one box - engineer Moray's way
☆* **Revealed At Last**: Ancient Invention Generates Energy-On-Demand
The design includes:

- Harnessing electricity from the Earth: Neither is Schumann Resonance, nor is it known by Electromagnetism. It's Energy from Ether in Which the Earth Floats
- Extracted from ordinary electricity by the method called “fractionation.”
- Reverse Tesla coil - "Back to Back" mechanism
- Combination of **radiant energy** and negative resistance to amplify electricity
- And many other plans for Free Energy.

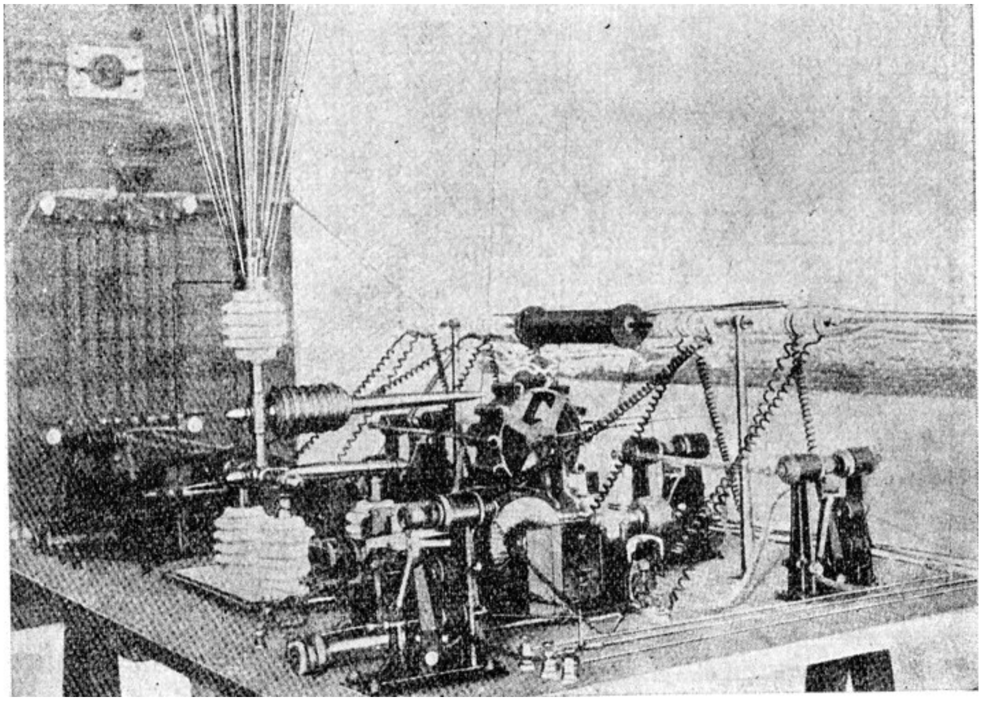
Update articles on radiant energy according to mainstream science: Radiant Energy - Moray Generator

Next we introduce another radiant energy version, in the style of capturing energy from the sky, like Tesla and Moray.

GUILLOT, Jules: Atmospheric Electric Generator -- A powerful proven design from the 1920s

The Guillot device generated about 2.5-3 Kilowatts with antenna height of ~ 20 meters. Power depends on the total collector surface and height of the vertical antenna. The apparatus in the photo produced ~300 watts with a collector 2 meters tall.



"Practical Utilization of Atmospheric Electricity"

by Gillbert Darida in *The Invention Encyclopedia,* pp. 204-207 (1930, Geo. Constantinescu, Ed.)

"The Earth has its own negative electricity, in the soil, and the atmosphere which surrounds the Earth is charged with positive electricity. The electric potential (the voltage) increases with the altitude, so we can say that the electric force is proportional to the atmospheric altitude (after Franklin, Quetelet, Lord Kelvin, Mascart, Joubert and other scientists).

The recent observations demonstrate that the air at 6000-7000 meters in altitude, is very highly charged with positive electricity, which could be explained by the friction between the external photosphere and the upper atmosphere of Earth, which rotates at a speed of more than 100,000 Kilometer per hour.

In that way, the Earth works like an electrostatic generator with electric charging by influence --- the upper atmosphere is positively charged by influence and the Earth crust obtains the negative polarity.

Between the two environments, the air and the soil, and inside the low atmosphere, in conditions of good weather, there are sbout 800 positive ions and also, 680 negative ion (and electrons) in just one square-centimeter of normal ionised air.

The Earth behaves like an huge electric armature negatively charged, which repels the electrons and attracts the positive ions. That positive ions' attraction determinates an electric current, also called "convective current". That's like an invisible continous bombardment, subject to daily and seasonal variations, which could be aproximated at **3 x 10 ^ -16 Amperes per square-centimeter,** and that is a total value of 1500 Amperes for the entire surface of the Earth.
The question is --- how does this current always maintains the same direction ? We can suppose that the natural radioactive emissions of the soil is responsable for this. We also know that radioactive emissions of the Earth works usually near the soil surface, and that explains the ionisation phenomenona inside caves.

The ionisation of the low atmosphere could also be the effect of the radioactive emissions of the Earth, especially when the X radiation works. Also, the Earth atmosphere is ionisated by the external radiation proceeding from the Sun and from the space environment, especially the action of ultraviolet radiation and the electron fascicles emitted by the Sun surface, at the temperature of 6000 deg. Celsius.

The capture of atmosphere electricity has been used in France, with aerial cables mounted on the Mont Blanc, and also in Germany --- with conductive cables carried by the captive baloons.

The atmosphere electricity collect system invented by eng. Jules Guillot is most ingenious and it relies on "the **electric siphon**" [*m.n. --- the discharging devices or spark-gap used today from the protection of aerial electric cables against the atmospheric electricity ; Jules Guillot has thought to recuperate and to use that electricity*].

His method consisted in the direct "pumping" of the atmosphere electricity using a collecting device which had two antennae and several collecting rods.

One antenna is **vertical** and it has a lot of **rods** scattered like an opened **fan**, with the tips against the **zenith**, for collecting the **negative** electricity which comes from the air ; the **horizontal** antenna is orientated against the **South** and its role is to collect the **positive** electricity.

The air electricity seems to have the double-polarity, as we can see at two electrised clouds when between them apears the electric discharge. The air could have different electric charging and the ionisation processus of atmosphere is very heterogenous. The inventor Guillot used **two separated and insulated armatures with the positive armature against the South** (more precisely, against the **Equator**...) and the **negative** armature against the **zenith**.

We can see in the scheme :

1,- the device P is the "**collector apparatus**" having **15-20 meters height** ; it also has a lot of **rods** which are scattered **fan**-like, all this on top of an **iron pillar** ; and also an **horizontal antenna** S oriented against the **South** ; the two antennae are disposed at **90 deg. angle** forming the two armatures where the electrical tension must apear. As the **height** of the pillar **increases**, the **voltage** increases more and more ;

2,- a system of **lightning-rods** (p1, p2, p3) for protection against discharges of atmospheric electricity during storms;

3,- the regulator system (**voltage regulator**, etc) R ;

4,- the electric **resistors** (Cn) for absorbing the parasite currents ;

5,- the "electric siphons" which have the role of making a magnetic field as a good environment for the transport of the ionized fluid, absorbing the electricity from the air ; the E1 and E2 are their regulator devices ;

6,- an **auxilliary continous current power supply** which send the current against an special **excitation coil**, used as starting device ; it works only when the system is starting.
This collector device works very good for lighting and heating. The device made by Guillot had
20 meters height on the total surface of **3 square-meters**. Also, J.Guillot used and electrical transformer for the industrial utilization of this "collector" --- as power supply for industrial electric engines."

French Patent # 551,882

Apparatus for Capture of Electric Currents in the Atmosphere

16 April 1923

Considering the terrestrial globe like the inductor of a dynamo, where the extraterrestrial ether is the inductor of electric currents circulating in the atmosphere; the apparatus of the invention described here selects through the device described below two perfectly distinct currents and eliminates others.

The device includes:

1, The air sensor; 2, a series of lightning rods; 3, vacuum; 4, an array of resistances; 5, vacuum; 6, witnesses.

1. An aerial sensor mounted on a pole is composed of **magnetic steel** fixed and sealed by a porcelain **insulator**, and surrounded a base by a **bronze ring** which are screwed **32 points of soft iron**, all forming antenna a pole. level beside it and isolated from the first, forming the 2nd pole, is fixed a sharp point of magnetic steel fixed in the horizontal position and directed towards the south and **movable to an angle of 45** is sealed in a porcelain insulator. This point is also circled a **ring of copper** notches figure. 1.

2. A series of 6 lightning surge arrestors at corners between each pole and the earth and the various gauges.

3. A first **regulator** form of a device similar absolutely similar to the aerial amtenna, but the two poles are superposed and opposed to the vertical point, and a **copper disk connects to ground**. Opposite the horizontal point, a **ring of tin** to which are welded tubes alternatively **16 tubes** composed each composed of **copper-lead** and **iron-lead** . The ring connects to the **ground** as shown in figure. 2.

A second regulator form of **automatic breakers** balanced on 3 poles and two poles also equally balanced.

4. A panel of **resistances** composed of **wire mesh** in bunches from different sections of **glass tubes** containing **copper** dust, **coal** and flowers of **sulfur**.

Vacuum cleaners consists of a **wooden box** on each pole, containing a **porcelain vase** in which **layers** isolated with **mica** is made up of **mercury, tin, coal, copper** and **sulfur**, all contaied in a **copper tube**.

6. The witnesses are comprised of ordinary incandescent lamps.

Resume

By the point at the zenith and the point to the south we channel two currents forming the two poles. We also protect from lightning. It regularizes the flow by a regulator and similar devices by a controlling each devise of adequate strength of the current harmful nature of these devices do not have loads. The refined current is conducted by ordinary copper wires**.**

French Patent # 565,395

Combined Apparatus for Capture of Atmospheric Electric Currents with Immediate Implementation

25 January 1924

We know that earth with its constitution, its rotation and movement in space, provides the electricity in the atmosphere. The electrical currents escape into space or largely accumulate towards the equator, as a result of the greater periphery of the globe.

In the atmosphere, there are two clearly distinct poles, i.e., clouds that can be electrically positive or negative; everything in nature shows this, otherwise it would be difficult to explain the lightning that occurs between the clouds and which are none other than contrary cloud electrical charges discharged by too close proximity.

The invention relates to a set of devices capable of capturing the atmospheric electricity.

So far, all searches made for this purpose has been to capture the atmosphere, i.e., that brought together into one system to capture two poles and opposes effect has been to destroy or cancel each other leaving the amount as the difference of the strongest to weakest.

It is therefore easy to understand why, considering the two poles of air as about equal, it is almost impossible to measure some potential with the land, the highest on the lowest remaining which can be positive or negative, copper being the strongest of one or other of these polarities.

It is on this basis that all research until now have been made, and that is why we must consider that all the time, between the two poles captured in the atmosphere and not in any mixture of systems uptake, it is possible to obtain tension and intensity, a considerable and measurable power captured separately between the two poles and remaining isolated from one another until their utilization .

In accordance with this invention, this collection is made by attraction of primary electrical currents in teh atmosphere, either positively or negatively charged, by an antenna that has two points absolutely isolated from one another, where one points to the zenith to attract negative electricity, and the other turned south, toward the equator to draws in the masses grouped in this area.

This shows and proves the existence of atmospheric electrical currents, and that it is possible to capture them with specially designed equipment primarily acting as regulators, as the persistent difficulty encountered so far in realizing their capture lies with large variations of tension in which the current atmosphere is present in space, for each of the poles, and an overload could inevitably fatal.

The patent in its present form of presentation does not cover the regulators or devices that are anticipated in the system, because they can be designed in different ways and give the same result, but covers the application and grouping of equipment operating as automatic relays with variable influence to limit current tension to that chosen for utilization.

These devices have a role associated with an overflow reservoir outside carrying excess liquid; these regulators will divert the excess voltage flows to ground.

We can still absorb these regulators having filters because they have the sole purpose of diverting the post being used , currents that are not yet known but likely that we will call for simplicity, abnormal currents. [sic...]

The patent also covers systems for regulating currents, applied to each of the poles because it is recognized that the shape and tension of the currents of the two poles are not equivalent.

The method of capture is by special antenna has directed two points in the atmosphere, as will be stated after this, with Boot ecoulement prior to the current atmosphere is also of great importance.

Finally, the current atmospheric reception is adequate even with the installation of a post, which can be expected at any location without the need for special altitude, as has been attempted in previous efforts.

We refer to the attached drawings:.

Figure 1 represents in elevation and side view an antenna that only has two points, to overcome an elevation ;

Figure 2 is the end of one of the peaks, the horizontal:

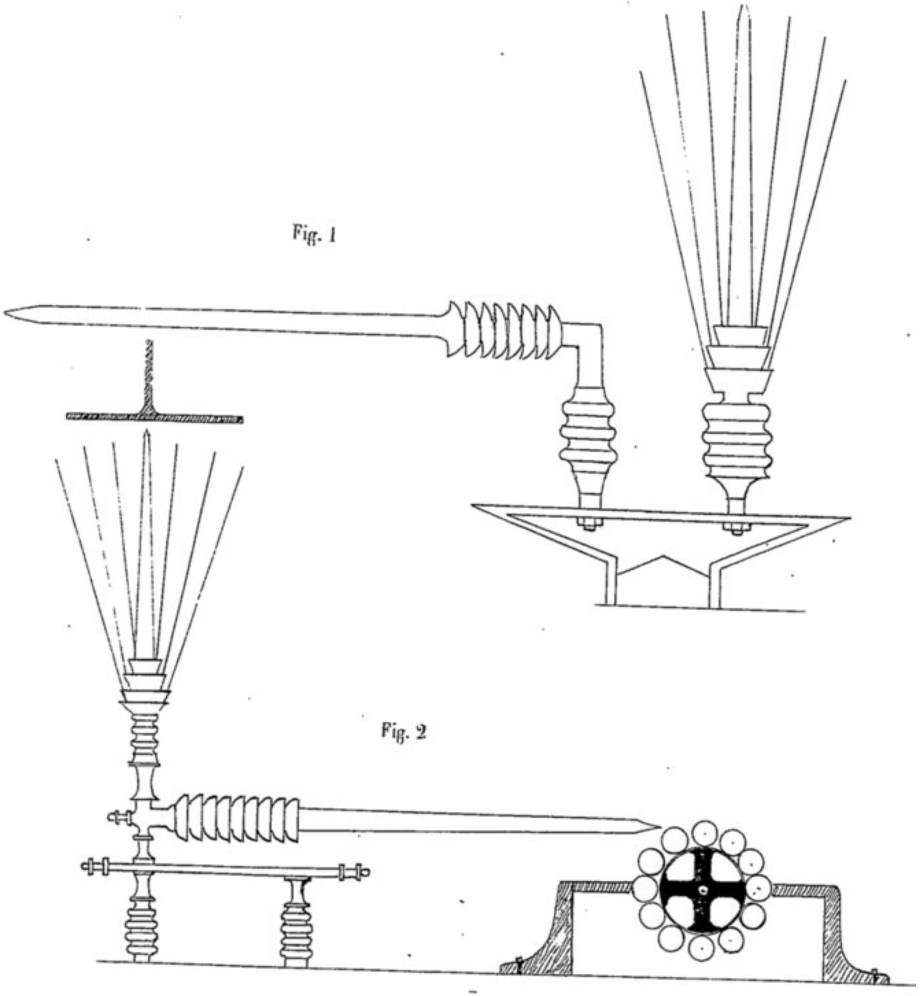


Figure 3 shows schematically the table on which are mounted various devices or accessories that act as regulators of current tensions.

Figure 4 is a scheme of surge arrestors, and

Figure 5 a table of resistances.

Fig. 4.

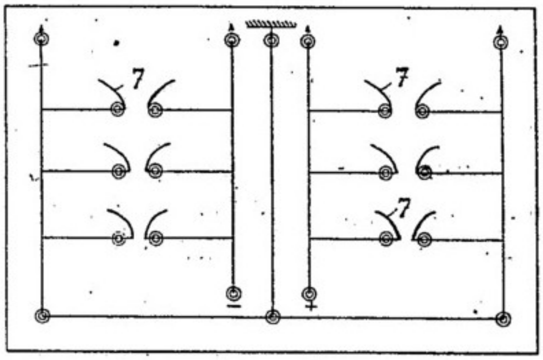

Fig. 5.

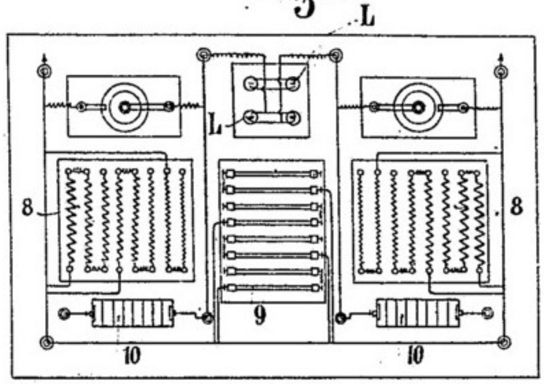


The necessary arrangements to capture atmospheric current form is as follows:

1. The **antenna** in figure 1 is formed with two peaks: the 1 is **steel**, supported by a **bronze ring** 2, surrounded by a **spiral form** 3; this point is oriented for attracting the **zenith** layers of **negative electricity** and the other edge 4 contains **copper coils** 6, and is oriented **south** to the **equator** to draw in the masses grouped in this area. To use this antenna it suffices to be raised on a mast or **pole** to a height a little higher than that of surrounding houses.

2. On the table **lightning arrestors**, contained 4, forms of 7 **copper horns** used to absorb large atmospheric discharges by certain time, as it would be dangerous to allow movement in the devices regulators.

3. On a table of **two** symmetrical systems **regulators**, Figure 3, one for each pole, to obtain and allow a regularization of large excesses in the current tensions, by automatically absorbing surges before passing over the surfacea chosen for the desired use. These regulators are represented on the drawing by the references R, R1, R2, R3, R4.

4. In the **resistance** panel in communication with regulators, these resistances are formed as **spiral coils or screens** 8, **tubes 9 of glass filled with fine coal dust , aluminum powder, sulfur and fine copper dust**. Finally, **two** special 10 **processors** and constitutes **layers** of metal forming an **absorbant** for harmful or abnormal currents.

5. As a source of energy formed **auxiliary batteries** 11 and **Ruhmkorff coils** 12 to get into the antenna sufficient attraction by means of an adjustment of intensity, which once it begins, allows the constant flow of atmospheric current in the system.

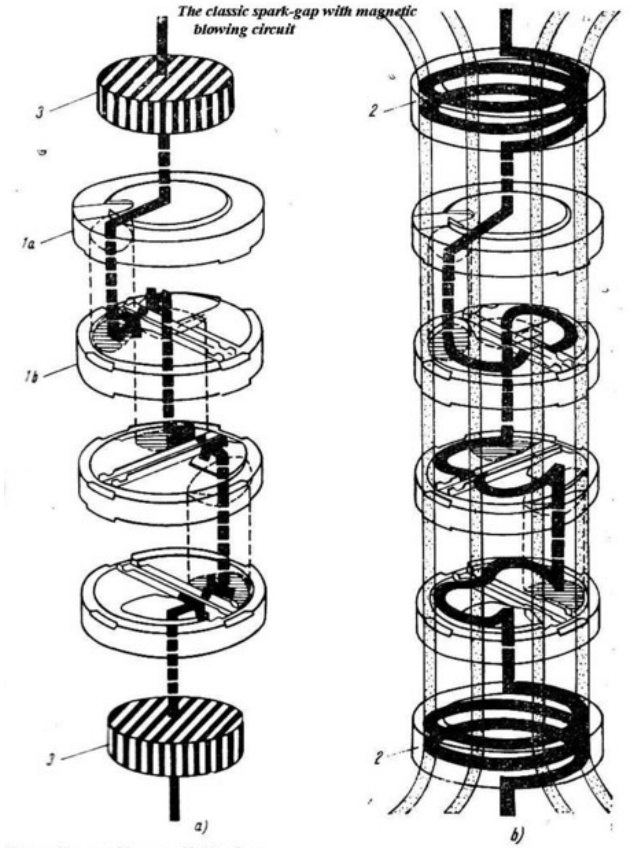
In considering Figure 3, which represents a sort of an installation scheme of the device, the reception of atmospheric electrical current will, as set out above, producing a priming of these currents. This boot is made in launching the system which is double to answer each of the poles, the current batteries 11 through 12 and reels going to the antenna.

This boot will continue until the disposal of electrical current atmosphere is evident by the one or more table lamps L of resistance shown in Figure 5.

Once the lights illuminate it is advisable to charge the batteries to boot. Natural flow and constant currents will be captured by the regulators , Figure 3; they will regularize in tension and in amperage and then directed to use in table lamps.

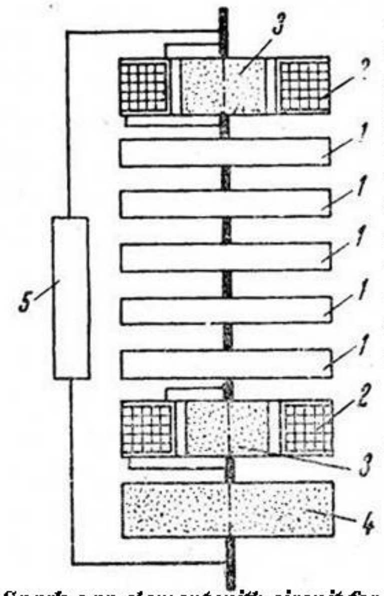
It has been said above that regulators R, etc., are intended and designed to automatically eliminate earth surge currents capture and abnormal currents that cannot yet be level but that these regulators could be replaced by devices with the same function.

There is therefore no need to describe in detail and especially the claims. We only specify that these regulators must be proper protection for the purposes described above.



The classic spark-gap with magnetic blowing circuit

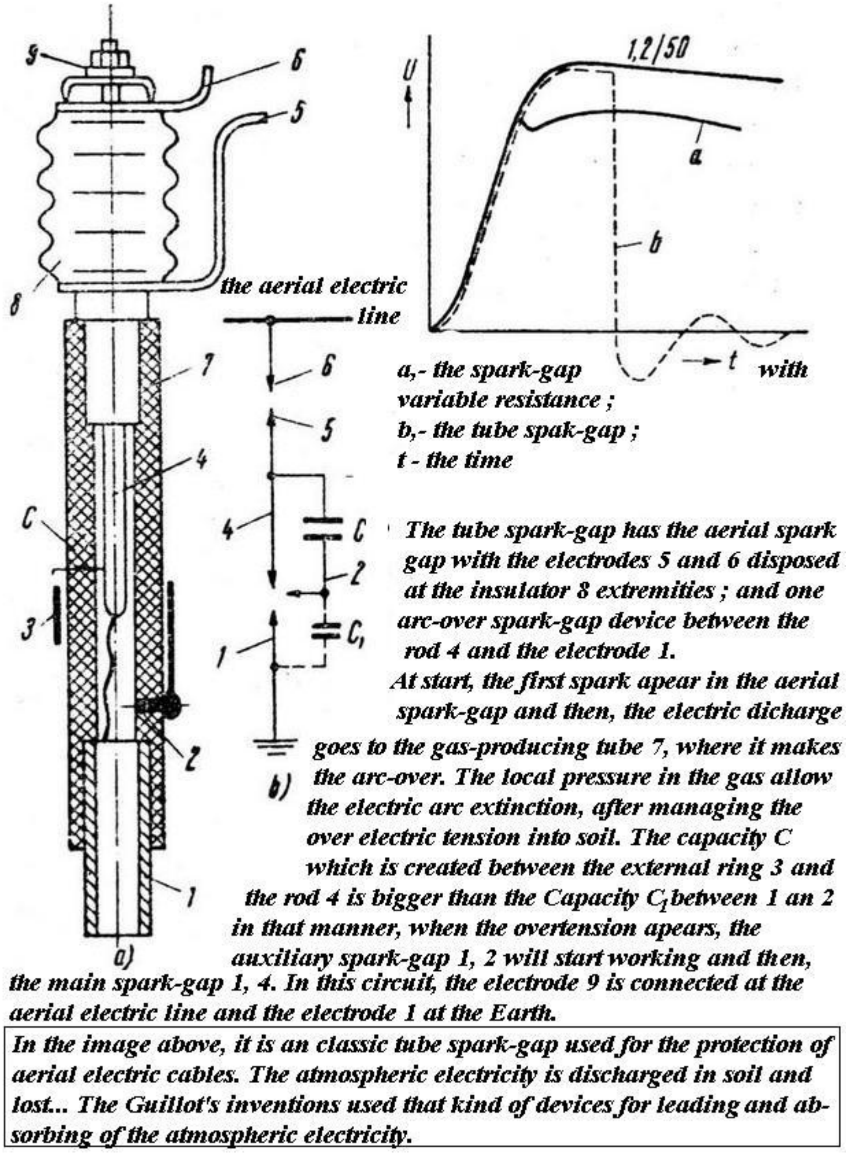
The spark-gap with magnetic blowing :
a,- the initial stage ; the impulse current send in soil through the shunt-resistences 3, because the coils 2 have an impedance too big for the impulse of 10/20 µs ;
the spark-gap 1 has two elements disc-shaped 1a and 1b, the inferior disc have one electrode and the upper disc the other electrode of the spark-gap circuit.
b,- the second stage ; the accompanying current discharge - after the impulse current ;
this accompanying current pass through the coils 2 which produce the magnetic field with the role to extend the electric arc into the slit between insulator discs 1a and 1b ; the thickness of this slit is smaller and smaller in accord with the extension of the electric arc, in this manner producing the magnifing of its electric resistance and finally, the electric arc extinction.



1,- the spark-gap individual devices which work in the manner to extend the electric arc of the accompanying electric current ;
2,- the coils which produce the magnetic field for the magnetic blowing ;
3,- the electric shunt-resistances in parallel connection on the blowing coils, with the role of reducing the current inside this coils
4,- the disc with unlinear resistance ;
5,- electrical resistance for the homogenous distribution of the electric field in all the elements of the spark-gap.

In Jules Guillot scheme, that kind of device could be used for leading the current.

Spark-gap element with circuit for the magnetic blowing of the electric fascicle

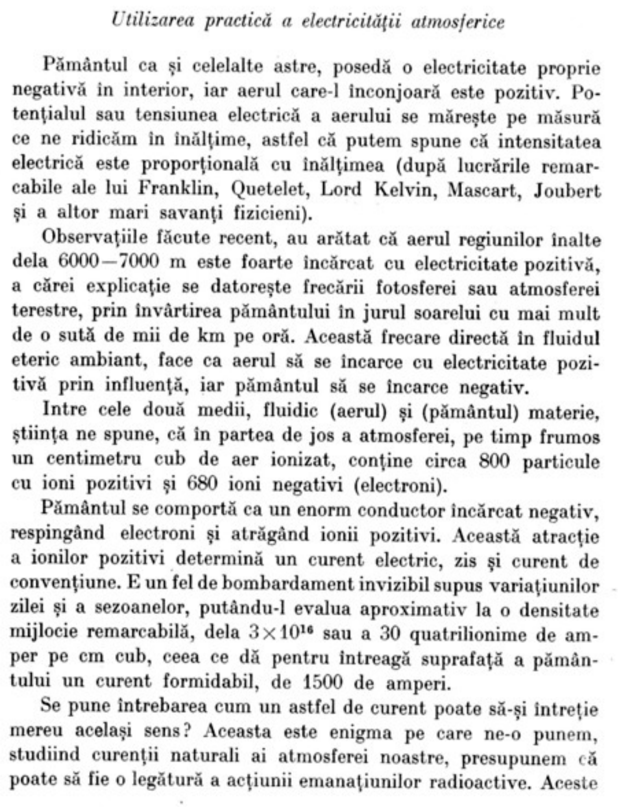


a,- the spark-gap with variable resistance ;
b,- the tube spak-gap ;
t - the time

The tube spark-gap has the aerial spark gap with the electrodes 5 and 6 disposed at the insulator 8 extremities ; and one arc-over spark-gap device between the rod 4 and the electrode 1.
At start, the first spark apear in the aerial spark-gap and then, the electric dicharge goes to the gas-producing tube 7, where it makes the arc-over. The local pressure in the gas allow the electric arc extinction, after managing the over electric tension into soil. The capacity C which is created between the external ring 3 and the rod 4 is bigger than the Capacity C_1 between 1 an 2 in that manner, when the overtension apears, the auxiliary spark-gap 1, 2 will start working and then, the main spark-gap 1, 4. In this circuit, the electrode 9 is connected at the aerial electric line and the electrode 1 at the Earth.

In the image above, it is an classic tube spark-gap used for the protection of aerial electric cables. The atmospheric electricity is discharged in soil and lost... The Guillot's inventions used that kind of devices for leading and absorbing of the atmospheric electricity.

DARIDA, Gillbert : "Practical Utilization of Atmospheric Electricity";
(in *The Invention Encyclopedia,* pp. 204-207 ; 1930, Geo. Constantinescu, Ed.) --



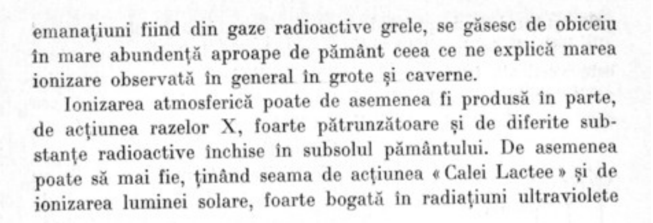
Pământul ca și celelalte astre, posedă o electricitate proprie negativă în interior, iar aerul care-l înconjoară este pozitiv. Potențialul sau tensiunea electrică a aerului se mărește pe măsură ce ne ridicăm în înălțime, astfel că putem spune că intensitatea electrică este proporțională cu înălțimea (după lucrările remarcabile ale lui Franklin, Quetelet, Lord Kelvin, Mascart, Joubert și a altor mari savanți fizicieni).

Observațiile făcute recent, au arătat că aerul regiunilor înalte dela 6000—7000 m este foarte încărcat cu electricitate pozitivă, a cărei explicație se datorește frecării fotosferei sau atmosferei terestre, prin învârtirea pământului în jurul soarelui cu mai mult de o sută de mii de km pe oră. Această frecare directă în fluidul eteric ambiant, face ca aerul să se încarce cu electricitate pozitivă prin influență, iar pământul să se încarce negativ.

Intre cele două medii, fluidic (aerul) și (pământul) materie, știința ne spune, că în partea de jos a atmosferei, pe timp frumos un centimetru cub de aer ionizat, conține circa 800 particule cu ioni pozitivi și 680 ioni negativi (electroni).

Pământul se comportă ca un enorm conductor încărcat negativ, respingând electroni și atrăgând ionii pozitivi. Această atracție a ionilor pozitivi determină un curent electric, zis și curent de convențiune. E un fel de bombardament invizibil supus variațiunilor zilei și a sezoanelor, putându-l evalua aproximativ la o densitate mijlocie remarcabilă, dela 3×10^{16} sau a 30 quatrilionime de amper pe cm cub, ceea ce dă pentru întreagă suprafață a pământului un curent formidabil, de 1500 de amperi.

Se pune întrebarea cum un astfel de curent poate să-și întreție mereu același sens? Aceasta este enigma pe care ne-o punem, studiind curenții naturali ai atmosferei noastre, presupunem că poate să fie o legătură a acțiunii emanațiunilor radioactive. Aceste



emanațiuni fiind din gaze radioactive grele, se găsesc de obiceiu în mare abundență aproape de pământ ceea ce ne explică marea ionizare observată în general în grote și caverne.

Ionizarea atmosferică poate de asemenea fi produsă în parte, de acțiunea razelor X, foarte pătrunzătoare și de diferite substanțe radioactive închise în subsolul pământului. De asemenea poate să mai fie, ținând seama de acțiunea «Calei Lactee» și de ionizarea luminei solare, foarte bogată în radiațiuni ultraviolete

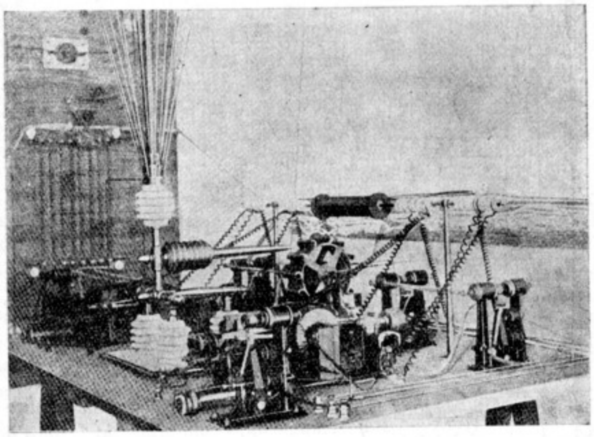


Fig. 108

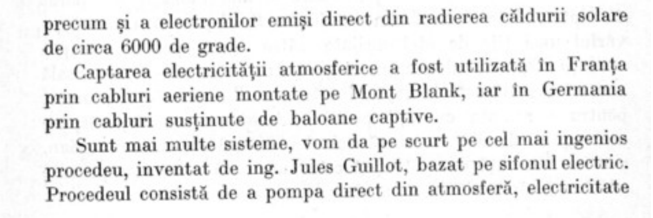
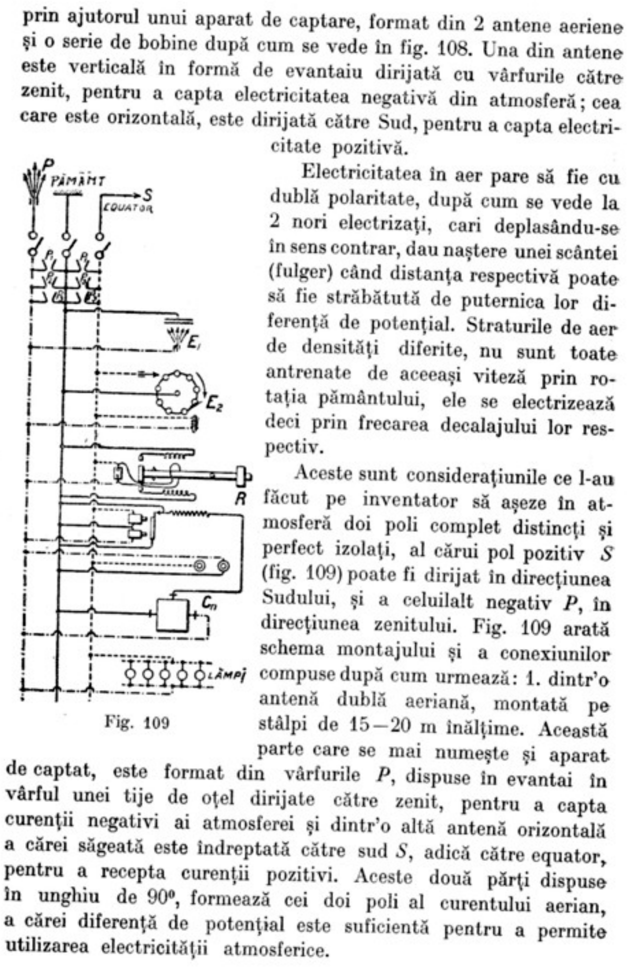


precum și a electronilor emiși direct din radierea căldurii solare de circa 6000 de grade.

Captarea electricității atmosferice a fost utilizată în Franța prin cabluri aeriene montate pe Mont Blank, iar în Germania prin cabluri susținute de baloane captive.

Sunt mai multe sisteme, vom da pe scurt pe cel mai ingenios procedeu, inventat de ing. Jules Guillot, bazat pe sifonul electric. Procedeul consistă de a pompa direct din atmosferă, electricitate



prin ajutorul unui aparat de captare, format din 2 antene aeriene şi o serie de bobine după cum se vede în fig. 108. Una din antene este verticală în formă de evantaiu dirijată cu vârfurile către zenit, pentru a capta electricitatea negativă din atmosferă; cea care este orizontală, este dirijată către Sud, pentru a capta electricitate pozitivă.

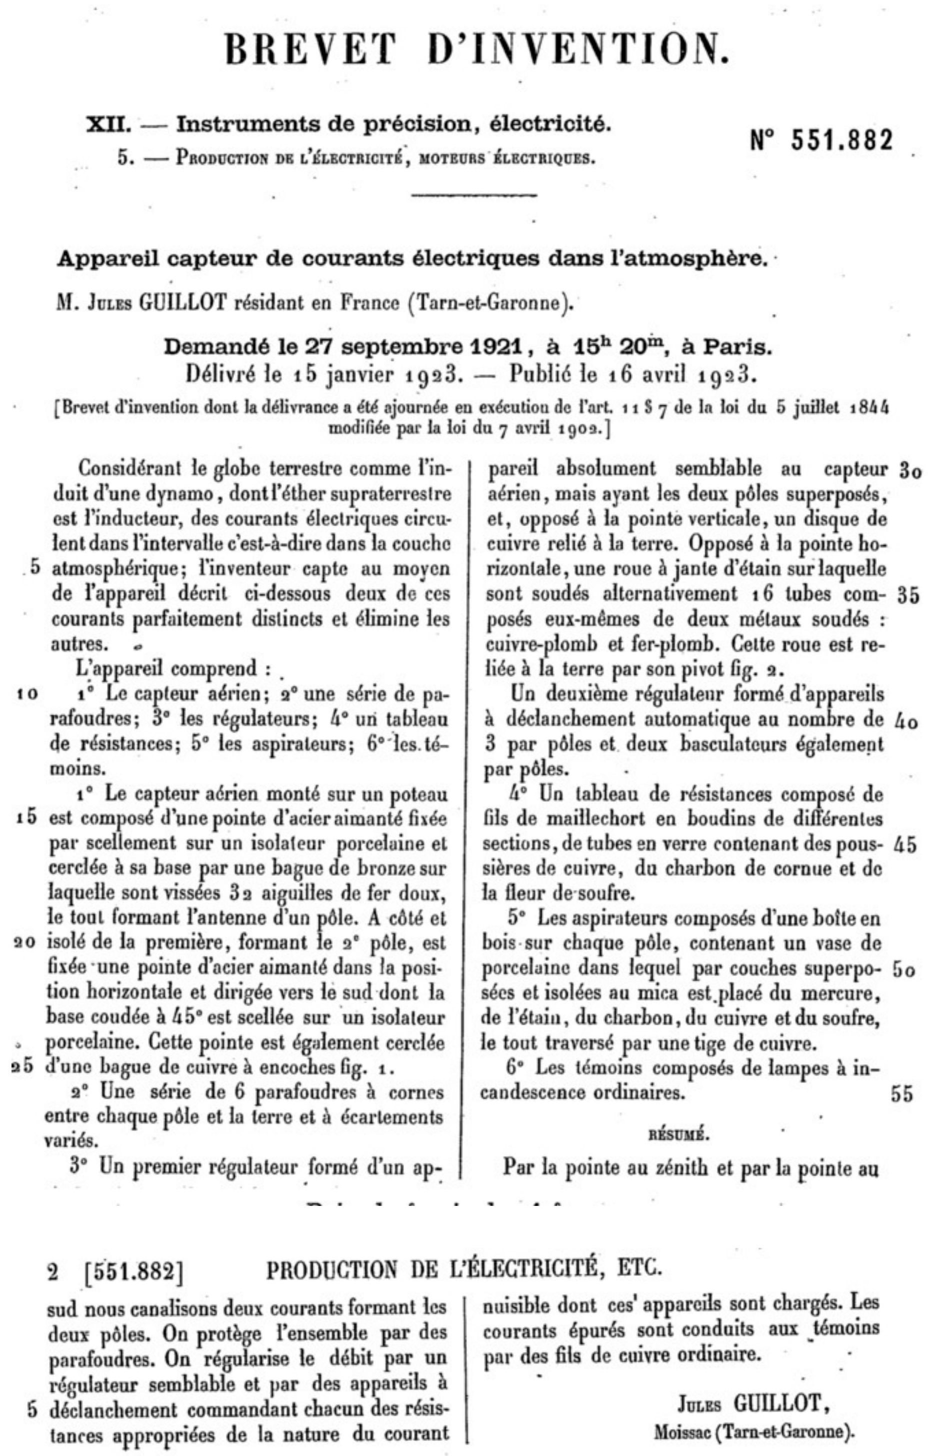
Electricitatea în aer pare să fie cu dublă polaritate, după cum se vede la 2 nori electrizaţi, cari deplasându-se în sens contrar, dau naştere unei scântei (fulger) când distanţa respectivă poate să fie străbătută de puternica lor diferenţă de potenţial. Straturile de aer de densităţi diferite, nu sunt toate antrenate de aceeaşi viteză prin rotaţia pământului, ele se electrizează deci prin frecarea decalajului lor respectiv.

Aceste sunt consideraţiunile ce l-au făcut pe inventator să aşeze în atmosferă doi poli complet distincţi şi perfect izolaţi, al cărui pol pozitiv *S* (fig. 109) poate fi dirijat în direcţiunea Sudului, şi a celuilalt negativ *P*, în direcţiunea zenitului. Fig. 109 arată schema montajului şi a conexiunilor compuse după cum urmează: 1. dintr'o antenă dublă aeriană, montată pe stâlpi de 15—20 m înălţime. Această parte care se mai numeşte şi aparat de captat, este format din vârfurile *P*, dispuse în evantai în vârful unei tije de oţel dirijate către zenit, pentru a capta curenţii negativi ai atmosferei şi dintr'o altă antenă orizontală a cărei săgeată este îndreptată către sud *S*, adică către equator, pentru a recepta curenţii pozitivi. Aceste două părţi dispuse în unghiu de 90°, formează cei doi poli al curentului aerian, a cărei diferenţă de potenţial este suficientă pentru a permite utilizarea electricităţii atmosferice.

Fig. 109

French Patent # 551,882

Appareil Capteur de Courants Electriques dans L'Atmosphere



BREVET D'INVENTION.

XII. — Instruments de précision, électricité.

5. — PRODUCTION DE L'ÉLECTRICITÉ, MOTEURS ÉLECTRIQUES.

N° 551.882

Appareil capteur de courants électriques dans l'atmosphère.

M. JULES GUILLOT résidant en France (Tarn-et-Garonne).

Demandé le 27 septembre 1921, à 15ʰ 20ᵐ, à Paris.
Délivré le 15 janvier 1923. — Publié le 16 avril 1923.
[Brevet d'invention dont la délivrance a été ajournée en exécution de l'art. 11 § 7 de la loi du 5 juillet 1844 modifiée par la loi du 7 avril 1902.]

Considérant le globe terrestre comme l'induit d'une dynamo, dont l'éther supraterrestre est l'inducteur, des courants électriques circulent dans l'intervalle c'est-à-dire dans la couche atmosphérique; l'inventeur capte au moyen de l'appareil décrit ci-dessous deux de ces courants parfaitement distincts et élimine les autres.

L'appareil comprend :

1° Le capteur aérien; 2° une série de parafoudres; 3° les régulateurs; 4° un tableau de résistances; 5° les aspirateurs; 6° les témoins.

1° Le capteur aérien monté sur un poteau est composé d'une pointe d'acier aimanté fixée par scellement sur un isolateur porcelaine et cerclée à sa base par une bague de bronze sur laquelle sont vissées 32 aiguilles de fer doux, le tout formant l'antenne d'un pôle. A côté et isolé de la première, formant le 2ᵉ pôle, est fixée une pointe d'acier aimanté dans la position horizontale et dirigée vers le sud dont la base coudée à 45° est scellée sur un isolateur porcelaine. Cette pointe est également cerclée d'une bague de cuivre à encoches fig. 1.

2° Une série de 6 parafoudres à cornes entre chaque pôle et la terre et à écartements variés.

3° Un premier régulateur formé d'un appareil absolument semblable au capteur aérien, mais ayant les deux pôles superposés, et, opposé à la pointe verticale, un disque de cuivre relié à la terre. Opposé à la pointe horizontale, une roue à jante d'étain sur laquelle sont soudés alternativement 16 tubes composés eux-mêmes de deux métaux soudés : cuivre-plomb et fer-plomb. Cette roue est reliée à la terre par son pivot fig. 2.

Un deuxième régulateur formé d'appareils à déclanchement automatique au nombre de 3 par pôles et deux basculateurs également par pôles.

4° Un tableau de résistances composé de fils de maillechort en boudins de différentes sections, de tubes en verre contenant des poussières de cuivre, du charbon de cornue et de la fleur de soufre.

5° Les aspirateurs composés d'une boîte en bois sur chaque pôle, contenant un vase de porcelaine dans lequel par couches superposées et isolées au mica est placé du mercure, de l'étain, du charbon, du cuivre et du soufre, le tout traversé par une tige de cuivre.

6° Les témoins composés de lampes à incandescence ordinaires.

RÉSUMÉ.

Par la pointe au zénith et par la pointe au sud nous canalisons deux courants formant les deux pôles. On protège l'ensemble par des parafoudres. On régularise le débit par un régulateur semblable et par des appareils à déclanchement commandant chacun des résistances appropriées de la nature du courant nuisible dont ces' appareils sont chargés. Les courants épurés sont conduits aux témoins par des fils de cuivre ordinaire.

JULES GUILLOT,
Moissac (Tarn-et-Garonne).

5. — Production de l'électricité, moteurs électriques.

N° 565.395

Dispositif combiné pour capter les courants électriques atmosphériques avec application immédiate.

M. Jules GUILLOT résidant en France (Allier).

Demandé le 6 avril 1923, à 11^{h} 30^{m}, à Paris.
Délivré le 7 novembre 1923. — Publié le 25 janvier 1924.

On sait que la terre, par sa propre constitution, sa rotation et son mouvement dans l'espace, fournit à elle seule l'électricité que l'on utilise et qui est en suspension dans l'atmosphère. Les courants électriques, qui s'échappent de la surface du globe, montent directement dans l'espace où les grandes masses sont accumulées vers l'équateur, par suite de la plus grande périphérie du globe.

Dans l'atmosphère, il y a deux pôles parfaitement distincts, c'est-à-dire que des nuages peuvent être électrisés, soit d'électricité positive ou négative; ceci, tout dans la nature le démontre, sans quoi, il serait difficile d'expliquer la provenance des éclairs qui se produisent entre les nuages et qui ne sont autres que des nuages chargés d'électricité contraire et qui s'amorcent entre eux par un trop grand rapprochement.

L'invention dont il s'agit concerne un dispositif formé d'un ensemble d'appareils aptes à la captation de ces courants atmosphériques.

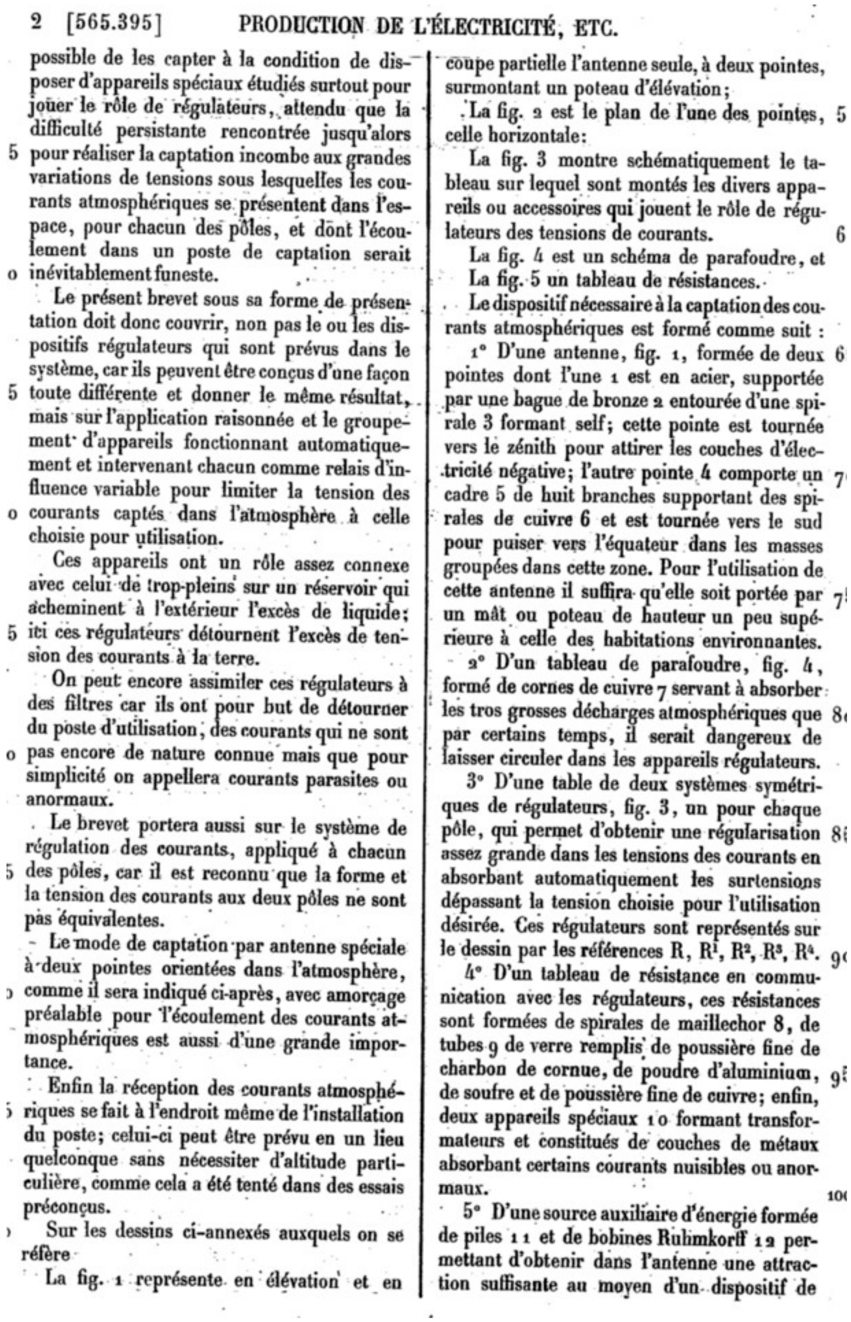
Jusqu'à ce jour, toutes les recherches faites dans ce but ont été de capter dans l'atmosphère une seule catégorie de courants atmosphériques, c'est-à-dire, qu'on a réuni dans un même système de captation, deux pôles opposés et dont l'effet a été de se détruire ou de s'annuler l'un à l'autre laissant comme quantité que la différence du plus fort au plus faible.

Il sera donc facile de comprendre pourquoi, en considérant les deux pôles d'un courant atmosphérique comme à peu près égaux, il est presque impossible par certains temps de mesurer le potentiel avec la terre, du plus fort sur le plus faible subsistant et qui peut être positif ou négatif, suivant que le plus fort est de l'une ou de l'autre de ces polarités.

C'est sur cette base que toutes les recherches jusqu'à nos jours ont été faites et c'est pourquoi, il faut considérer que par tous les temps, entre les deux pôles captés dans l'atmosphère et non mélangés dans aucun des systèmes de captation, il est possible d'obtenir, en tension et en intensité, une puissance aussi considérable que l'on puisse désirer et qui sera mesurée entre les deux pôles captés séparément et toujours isolés l'un de l'autre jusqu'à leur utilisation.

Suivant l'invention, cette captation se fait par attraction dans l'atmosphère au moyen d'un amorçage des courants électriques, soit positif ou négatif, par une antenne à deux pointes absolument isolées l'une de l'autre, dont l'une tournée vers le zénith attire les couches d'électricité négative, et l'autre, tournée vers le sud, puise vers l'équateur, dans les masses groupées dans cette zone.

Ceci exposé et l'existence des courants électriques atmosphériques étant prouvée, il est



possible de les capter à la condition de disposer d'appareils spéciaux étudiés surtout pour jouer le rôle de régulateurs, attendu que la difficulté persistante rencontrée jusqu'alors pour réaliser la captation incombe aux grandes variations de tensions sous lesquelles les courants atmosphériques se présentent dans l'espace, pour chacun des pôles, et dont l'écoulement dans un poste de captation serait inévitablement funeste.

Le présent brevet sous sa forme de présentation doit donc couvrir, non pas le ou les dispositifs régulateurs qui sont prévus dans le système, car ils peuvent être conçus d'une façon toute différente et donner le même résultat, mais sur l'application raisonnée et le groupement d'appareils fonctionnant automatiquement et intervenant chacun comme relais d'influence variable pour limiter la tension des courants captés dans l'atmosphère à celle choisie pour utilisation.

Ces appareils ont un rôle assez connexe avec celui de trop-pleins sur un réservoir qui acheminent à l'extérieur l'excès de liquide; ici ces régulateurs détournent l'excès de tension des courants à la terre.

On peut encore assimiler ces régulateurs à des filtres car ils ont pour but de détourner du poste d'utilisation, des courants qui ne sont pas encore de nature connue mais que pour simplicité on appellera courants parasites ou anormaux.

Le brevet portera aussi sur le système de régulation des courants, appliqué à chacun des pôles, car il est reconnu que la forme et la tension des courants aux deux pôles ne sont pas équivalentes.

Le mode de captation par antenne spéciale à deux pointes orientées dans l'atmosphère, comme il sera indiqué ci-après, avec amorçage préalable pour l'écoulement des courants atmosphériques est aussi d'une grande importance.

Enfin la réception des courants atmosphériques se fait à l'endroit même de l'installation du poste; celui-ci peut être prévu en un lieu quelconque sans nécessiter d'altitude particulière, comme cela a été tenté dans des essais préconçus.

Sur les dessins ci-annexés auxquels on se réfère

La fig. 1 représente en élévation et en coupe partielle l'antenne seule, à deux pointes, surmontant un poteau d'élévation;

La fig. 2 est le plan de l'une des pointes, celle horizontale:

La fig. 3 montre schématiquement le tableau sur lequel sont montés les divers appareils ou accessoires qui jouent le rôle de régulateurs des tensions de courants.

La fig. 4 est un schéma de parafoudre, et

La fig. 5 un tableau de résistances.

Le dispositif nécessaire à la captation des courants atmosphériques est formé comme suit :

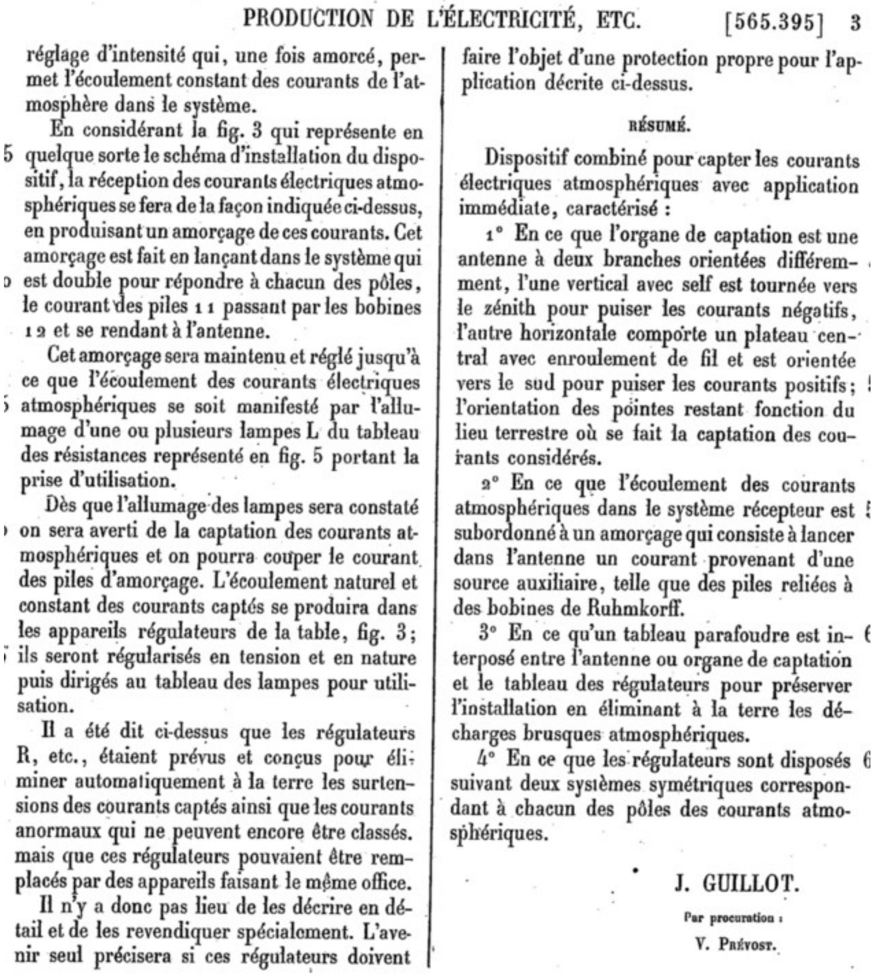
1° D'une antenne, fig. 1, formée de deux pointes dont l'une 1 est en acier, supportée par une bague de bronze 2 entourée d'une spirale 3 formant self; cette pointe est tournée vers le zénith pour attirer les couches d'électricité négative; l'autre pointe 4 comporte un cadre 5 de huit branches supportant des spirales de cuivre 6 et est tournée vers le sud pour puiser vers l'équateur dans les masses groupées dans cette zone. Pour l'utilisation de cette antenne il suffira qu'elle soit portée par un mât ou poteau de hauteur un peu supérieure à celle des habitations environnantes.

2° D'un tableau de parafoudre, fig. 4, formé de cornes de cuivre 7 servant à absorber les tros grosses décharges atmosphériques que par certains temps, il serait dangereux de laisser circuler dans les appareils régulateurs.

3° D'une table de deux systèmes symétriques de régulateurs, fig. 3, un pour chaque pôle, qui permet d'obtenir une régularisation assez grande dans les tensions des courants en absorbant automatiquement les surtensions dépassant la tension choisie pour l'utilisation désirée. Ces régulateurs sont représentés sur le dessin par les références R, R^1, R^2, R^3, R^4.

4° D'un tableau de résistance en communication avec les régulateurs, ces résistances sont formées de spirales de maillechor 8, de tubes 9 de verre remplis de poussière fine de charbon de cornue, de poudre d'aluminium, de soufre et de poussière fine de cuivre; enfin, deux appareils spéciaux 10 formant transformateurs et constitués de couches de métaux absorbant certains courants nuisibles ou anormaux.

5° D'une source auxiliaire d'énergie formée de piles 11 et de bobines Ruhmkorff 12 permettant d'obtenir dans l'antenne une attraction suffisante au moyen d'un dispositif de



réglage d'intensité qui, une fois amorcé, permet l'écoulement constant des courants de l'atmosphère dans le système.

En considérant la fig. 3 qui représente en quelque sorte le schéma d'installation du dispositif, la réception des courants électriques atmosphériques se fera de la façon indiquée ci-dessus, en produisant un amorçage de ces courants. Cet amorçage est fait en lançant dans le système qui est double pour répondre à chacun des pôles, le courant des piles 11 passant par les bobines 12 et se rendant à l'antenne.

Cet amorçage sera maintenu et réglé jusqu'à ce que l'écoulement des courants électriques atmosphériques se soit manifesté par l'allumage d'une ou plusieurs lampes L du tableau des résistances représenté en fig. 5 portant la prise d'utilisation.

Dès que l'allumage des lampes sera constaté on sera averti de la captation des courants atmosphériques et on pourra couper le courant des piles d'amorçage. L'écoulement naturel et constant des courants captés se produira dans les appareils régulateurs de la table, fig. 3; ils seront régularisés en tension et en nature puis dirigés au tableau des lampes pour utilisation.

Il a été dit ci-dessus que les régulateurs R, etc., étaient prévus et conçus pour éliminer automatiquement à la terre les surtensions des courants captés ainsi que les courants anormaux qui ne peuvent encore être classés. mais que ces régulateurs pouvaient être remplacés par des appareils faisant le même office.

Il n'y a donc pas lieu de les décrire en détail et de les revendiquer spécialement. L'avenir seul précisera si ces régulateurs doivent faire l'objet d'une protection propre pour l'application décrite ci-dessus.

RÉSUMÉ.

Dispositif combiné pour capter les courants électriques atmosphériques avec application immédiate, caractérisé :

1° En ce que l'organe de captation est une antenne à deux branches orientées différemment, l'une vertical avec self est tournée vers le zénith pour puiser les courants négatifs, l'autre horizontale comporte un plateau central avec enroulement de fil et est orientée vers le sud pour puiser les courants positifs; l'orientation des pointes restant fonction du lieu terrestre où se fait la captation des courants considérés.

2° En ce que l'écoulement des courants atmosphériques dans le système récepteur est subordonné à un amorçage qui consiste à lancer dans l'antenne un courant provenant d'une source auxiliaire, telle que des piles reliées à des bobines de Ruhmkorff.

3° En ce qu'un tableau parafoudre est interposé entre l'antenne ou organe de captation et le tableau des régulateurs pour préserver l'installation en éliminant à la terre les décharges brusques atmosphériques.

4° En ce que les régulateurs sont disposés suivant deux systèmes symétriques correspondant à chacun des pôles des courants atmosphériques.

J. GUILLOT.

The Guillot device generated about 2.5-3 Kilowatts with antenna height of ~ 20 meters. Power depends on the total collector surface and height of the vertical antenna. The apparatus in the photo produced ~300 watts with a collector 2 meters tall.

"Practical Utilization of Atmospheric Electricity"

by

Gillbert Darida

in *The Invention Encyclopedia,* pp. 204-207 (1930, Geo. Constantinescu, Ed.)

"The Earth has its own negative electricity, in the soil, and the atmosphere which surrounds the Earth is charged with positive electricity. The electric potential (the voltage) increases with the altitude, so we can say that the electric force is proportional to the atmospheric altitude (after Franklin, Quetelet, Lord Kelvin, Mascart, Joubert and other scientists).

The recent observations demonstrate that the air at 6000-7000 meters in altitude, is very highly charged with positive electricity, which could be explained by the friction between the external photosphere and the upper atmosphere of Earth, which rotates at a speed of more than 100,000 Kilometer per hour.

In that way, the Earth works like an electrostatic generator with electric charging by influence --- the upper atmosphere is positively charged by influence and the Earth crust obtains the negative polarity.

Between the two environments, the air and the soil, and inside the low atmosphere, in conditions of good weather, there are sbout 800 positive ions and also, 680 negative ion (and electrons) in just one square-centimeter of normal ionised air.

The Earth behaves like an huge electric armature negatively charged, which repels the electrons and attracts the positive ions. That positive ions' attraction determinates an electric current, also called "convective current". That's like an invisible continous bombardment, subject to daily and seasonal variations, which could be aproximated at **3 x 10 ^ -16 Amperes per square-centimeter,** and that is a total value of 1500 Amperes for the entire surface of the Earth.
The question is --- how does this current always maintains the same direction ? We can suppose that the natural radioactive emissions of the soil is responsable for this. We also know that radioactive emissions of the Earth works usually near the soil surface, and that explains the ionisation phenomenona inside caves.

The ionisation of the low atmosphere could also be the effect of the radioactive emissions of the Earth, especially when the X radiation works. Also, the Earth atmosphere is ionisated by the external radiation proceeding from the Sun and from the space environment, especially the action of ultraviolet radiation and the electron fascicles emitted by the Sun surface, at the temperature of 6000 deg. Celsius.

The capture of atmosphere electricity has been used in France, with aerial cables mounted on the Mont Blanc, and also in Germany --- with conductive cables carried by the captive baloons.

The atmosphere electricity collect system invented by eng. Jules Guillot is most ingenious and it relies on "the **electric siphon**" [*m.n. --- the discharging devices or spark-gap used today from the protection of aerial electric cables against the atmospheric electricity ; Jules Guillot has thought to recuperate and to use that electricity*].

His method consisted in the direct "pumping" of the atmosphere electricity using a collecting device which had two antennae and several collecting rods.

One antenna is **vertical** and it has a lot of **rods** scattered like an opened **fan**, with the tips against the **zenith**, for collecting the **negative** electricity which comes from the air ; the **horizontal** antenna is orientated against the **South** and its role is to collect the **positive** electricity.

The air electricity seems to have the double-polarity, as we can see at two electrised clouds when between them apears the electric discharge. The air could have different electric charging and the ionisation processus of atmosphere is very heterogenous. The inventor Guillot used **two separated and insulated armatures with the positive armature against the South** (more precisely, against the **Equator**...) and the **negative** armature against the **zenith**.

We can see in the scheme :

1,- the device P is the "**collector apparatus**" having **15-20 meters height** ; it also has a lot of **rods** which are scattered **fan**-like, all this on top of an **iron pillar** ; and also an **horizontal antenna** S oriented against the **South** ; the two antennae are disposed at **90 deg. angle** forming the two armatures where the electrical tension must apear. As the **height** of the pillar **increases**, the **voltage** increases more and more ;

2,- a system of **lightning-rods** (p1, p2, p3) for protection against discharges of atmospheric electricity during storms;

3,- the regulator system (**voltage regulator**, etc) R ;

4,- the electric **resistors** (Cn) for absorbing the parasite currents ;

5,- the "electric siphons" which have the role of making a magnetic field as a good environment for the transport of the ionized fluid, absorbing the electricity from the air ; the E1 and E2 are their regulator devices ;

6,- an **auxilliary continous current power supply** which send the current against an special **excitation coil**, used as starting device ; it works only when the system is starting.
This collector device works very good for lighting and heating. The device made by Guillot had **20 meters height** on the total surface of **3 square-meters**. Also, J.Guillot used and electrical transformer for the industrial utilization of this "collector" --- as power supply for industrial electric engines."

French Patent # 551,882

Apparatus for Capture of Electric Currents in the Atmosphere

16 April 1923

Considering the terrestrial globe like the inductor of a dynamo, where the extraterrestrial ether is the inductor of electric currents circulating in the atmosphere; the apparatus of the invention described here selects through the device described below two perfectly distinct currents and eliminates others.

The device includes:

1, The air sensor; 2, a series of lightning rods; 3, vacuum; 4, an array of resistances; 5, vacuum; 6, witnesses.

1. An aerial sensor mounted on a pole is composed of **magnetic steel** fixed and sealed by a porcelain **insulator**, and surrounded a base by a **bronze ring** which are screwed **32 points of soft iron**, all forming antenna a pole. level beside it and isolated from the first, forming the 2nd pole, is fixed a sharp point of magnetic steel fixed in the horizontal position and directed towards the south and **movable to an angle of 45** is sealed in a porcelain insulator. This point is also circled a **ring of copper** notches figure. 1.

2. A series of 6 lightning surge arrestors at corners between each pole and the earth and the various gauges.

3. A first **regulator** form of a device similar absolutely similar to the aerial amtenna, but the two poles are superposed and opposed to the vertical point, and a **copper disk connects to ground**. Opposite the horizontal point, a **ring of tin** to which are welded tubes alternatively **16 tubes** composed each composed of **copper-lead** and **iron-lead** . The ring connects to the **ground** as shown in figure. 2.

A second regulator form of **automatic breakers** balanced on 3 poles and two poles also equally balanced.

4. A panel of **resistances** composed of **wire mesh** in bunches from different sections of **glass tubes** containing **copper** dust, **coal** and flowers of **sulfur**.

Vacuum cleaners consists of a **wooden box** on each pole, containing a **porcelain vase** in which **layers** isolated with **mica** is made up of **mercury, tin, coal, copper** and **sulfur**, all contaied in a **copper tube**.

6. The witnesses are comprised of ordinary incandescent lamps.

Resume

By the point at the zenith and the point to the south we channel two currents forming the two poles. We also protect from lightning. It regularizes the flow by a regulator and similar devices by a controlling each devise of adequate strength of the current harmful nature of these devices do not have loads. The refined current is conducted by ordinary copper wires**.**

French Patent # 565,395

Combined Apparatus for Capture of Atmospheric Electric Currents with Immediate Implementation

25 January 1924

We know that earth with its constitution, its rotation and movement in space, provides the electricity in the atmosphere. The electrical currents escape into space or largely accumulate towards the equator, as a result of the greater periphery of the globe.

In the atmosphere, there are two clearly distinct poles, i.e., clouds that can be electrically positive or negative; everything in nature shows this, otherwise it would be difficult to explain the lightning that occurs between the clouds and which are none other than contrary cloud electrical charges discharged by too close proximity.

The invention relates to a set of devices capable of capturing the atmospheric electricity.

So far, all searches made for this purpose has been to capture the atmosphere, i.e., that brought together into one system to capture two poles and opposes effect has been to destroy or cancel each other leaving the amount as the difference of the strongest to weakest.

It is therefore easy to understand why, considering the two poles of air as about equal, it is almost impossible to measure some potential with the land, the highest on the lowest remaining which can be positive or negative, copper being the strongest of one or other of these polarities.

It is on this basis that all research until now have been made, and that is why we must consider that all the time, between the two poles captured in the atmosphere and not in any mixture of systems uptake, it is possible to obtain tension and intensity, a considerable and measurable power captured separately between the two poles and remaining isolated from one another until their utilization .

In accordance with this invention, this collection is made by attraction of primary electrical currents in teh atmosphere, either positively or negatively charged, by an antenna that has two points absolutely isolated from one another, where one points to the zenith to attract negative electricity, and the other turned south, toward the equator to draws in the masses grouped in this area.

This shows and proves the existence of atmospheric electrical currents, and that it is possible to capture them with specially designed equipment primarily acting as regulators, as the persistent difficulty encountered so far in realizing their capture lies with large variations of tension in which the current atmosphere is present in space, for each of the poles, and an overload could inevitably fatal.

The patent in its present form of presentation does not cover the regulators or devices that are anticipated in the system, because they can be designed in different ways and give the same result, but covers the application and grouping of equipment operating as automatic relays with variable influence to limit current tension to that chosen for utilization.

These devices have a role associated with an overflow reservoir outside carrying excess liquid; these regulators will divert the excess voltage flows to ground.

We can still absorb these regulators having filters because they have the sole purpose of diverting the post being used , currents that are not yet known but likely that we will call for simplicity, abnormal currents. [sic...]

The patent also covers systems for regulating currents, applied to each of the poles because it is recognized that the shape and tension of the currents of the two poles are not equivalent.

The method of capture is by special antenna has directed two points in the atmosphere, as will be stated after this, with Boot ecoulement prior to the current atmosphere is also of great importance.

Finally, the current atmospheric reception is adequate even with the installation of a post, which can be expected at any location without the need for special altitude, as has been attempted in previous efforts.

We refer to the attached drawings:.

Figure 1 represents in elevation and side view an antenna that only has two points, to overcome an elevation ;

Figure 2 is the end of one of the peaks, the horizontal:

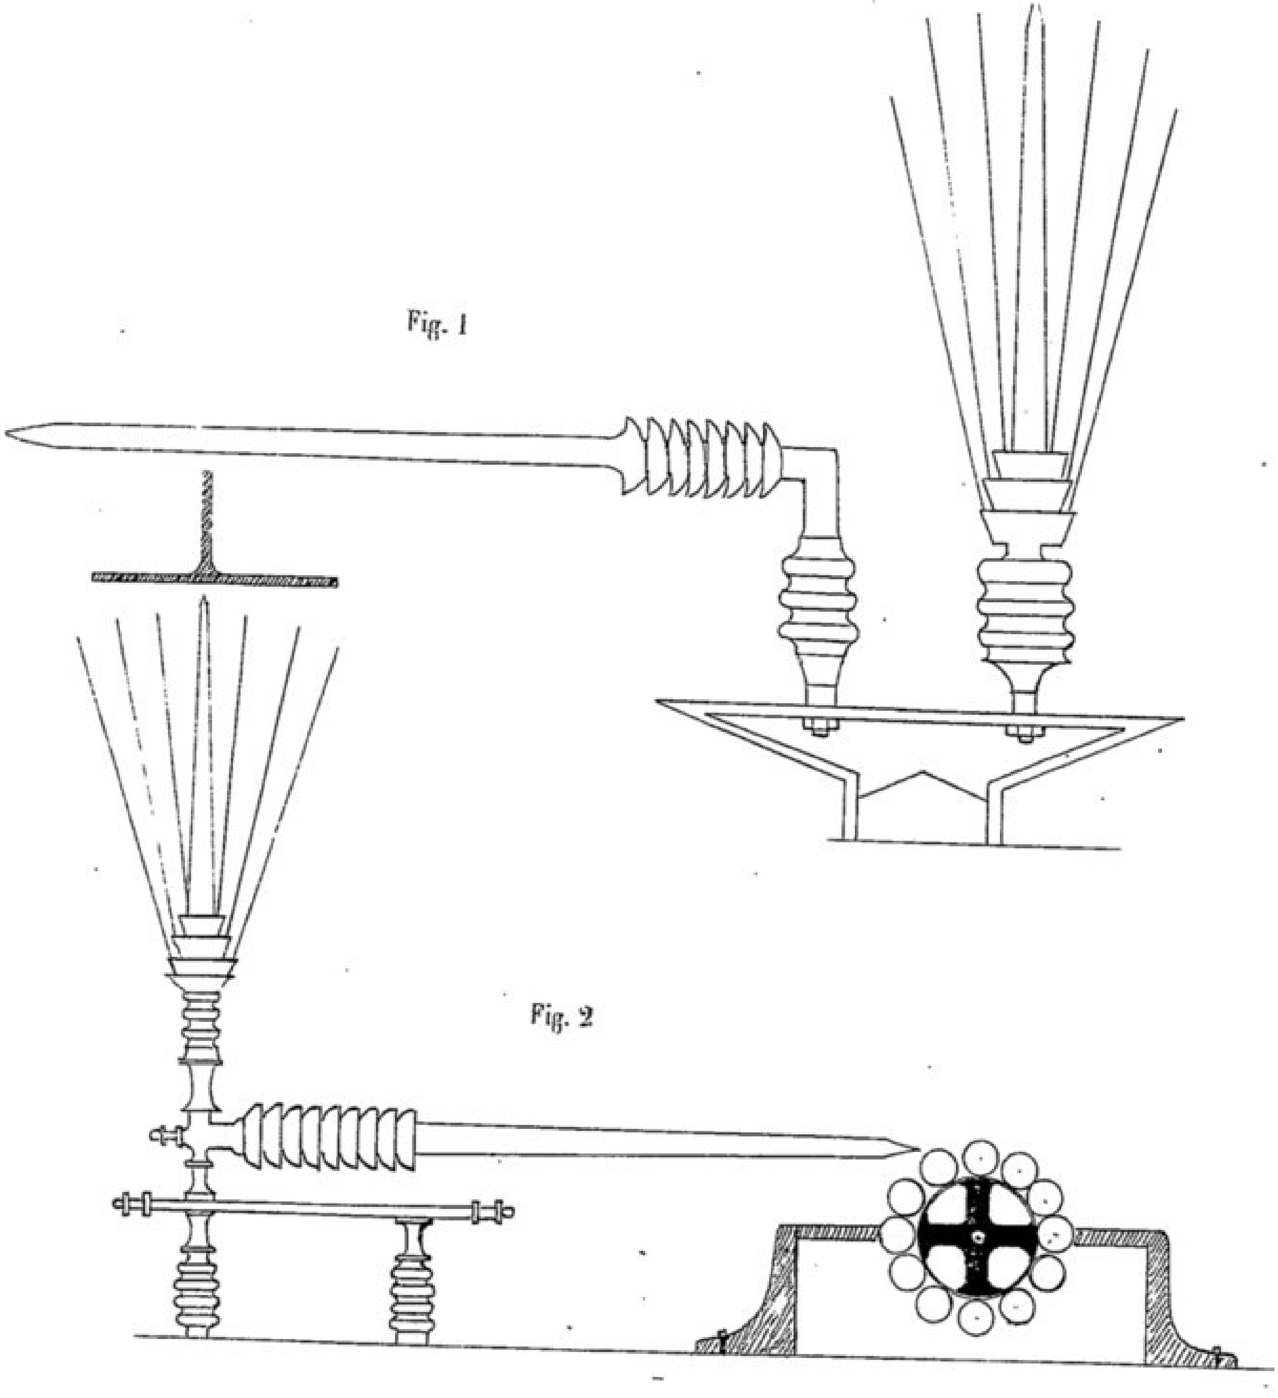

Fig. 1

Fig. 2

Figure 3 shows schematically the table on which are mounted various devices or accessories that act as regulators of current tensions.

Figure 4 is a scheme of surge arrestors, and

Figure 5 a table of resistances.

Fig. 4.

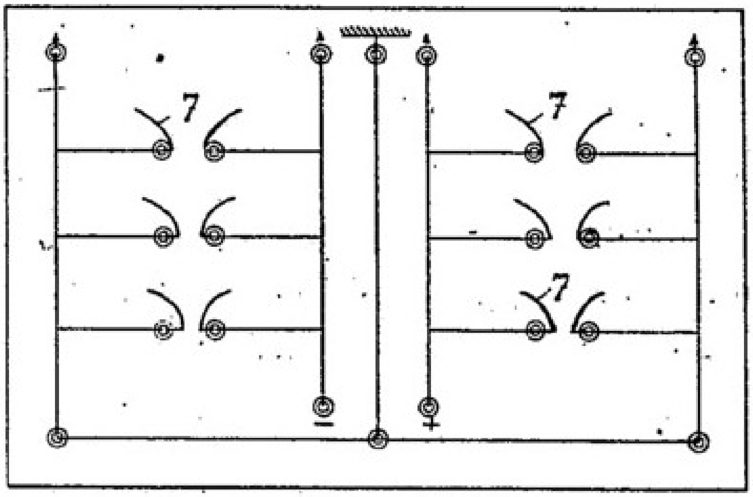

Fig. 5.

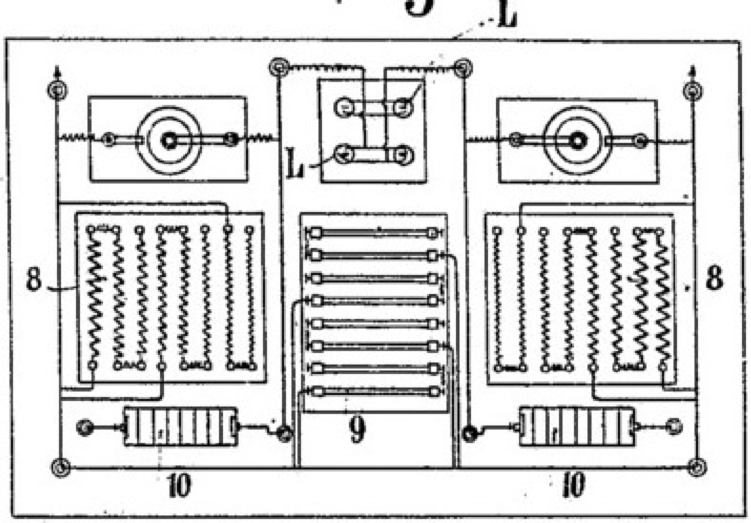


The necessary arrangements to capture atmospheric current form is as follows:

1. The **antenna** in figure 1 is formed with two peaks: the 1 is **steel**, supported by a **bronze ring** 2, surrounded by a **spiral form** 3; this point is oriented for attracting the **zenith** layers of **negative electricity** and the other edge 4 contains **copper coils** 6, and is oriented **south** to the **equator** to draw in the masses grouped in this area. To use this antenna it suffices to be raised on a mast or **pole** to a height a little higher than that of surrounding houses.

2. On the table **lightning arrestors**, contained 4, forms of 7 **copper horns** used to absorb large atmospheric discharges by certain time, as it would be dangerous to allow movement in the devices regulators.

3. On a table of **two** symmetrical systems **regulators**, Figure 3, one for each pole, to obtain and allow a regularization of large excesses in the current tensions, by automatically absorbing surges before passing over the surfacea chosen for the desired use. These regulators are represented on the drawing by the references R, R1, R2, R3, R4.

4. In the **resistance** panel in communication with regulators, these resistances are formed as **spiral coils or screens** 8, **tubes 9 of glass filled with fine coal dust , aluminum powder, sulfur and fine copper dust**. Finally, **two** special 10 **processors** and constitutes **layers** of metal forming an **absorbant** for harmful or abnormal currents.

5. As a source of energy formed **auxiliary batteries** 11 and **Ruhmkorff coils** 12 to get into the antenna sufficient attraction by means of an adjustment of intensity, which once it begins, allows the constant flow of atmospheric current in the system.

In considering Figure 3, which represents a sort of an installation scheme of the device, the reception of atmospheric electrical current will, as set out above, producing a priming of these currents. This boot is made in launching the system which is double to answer each of the poles, the current batteries 11 through 12 and reels going to the antenna.

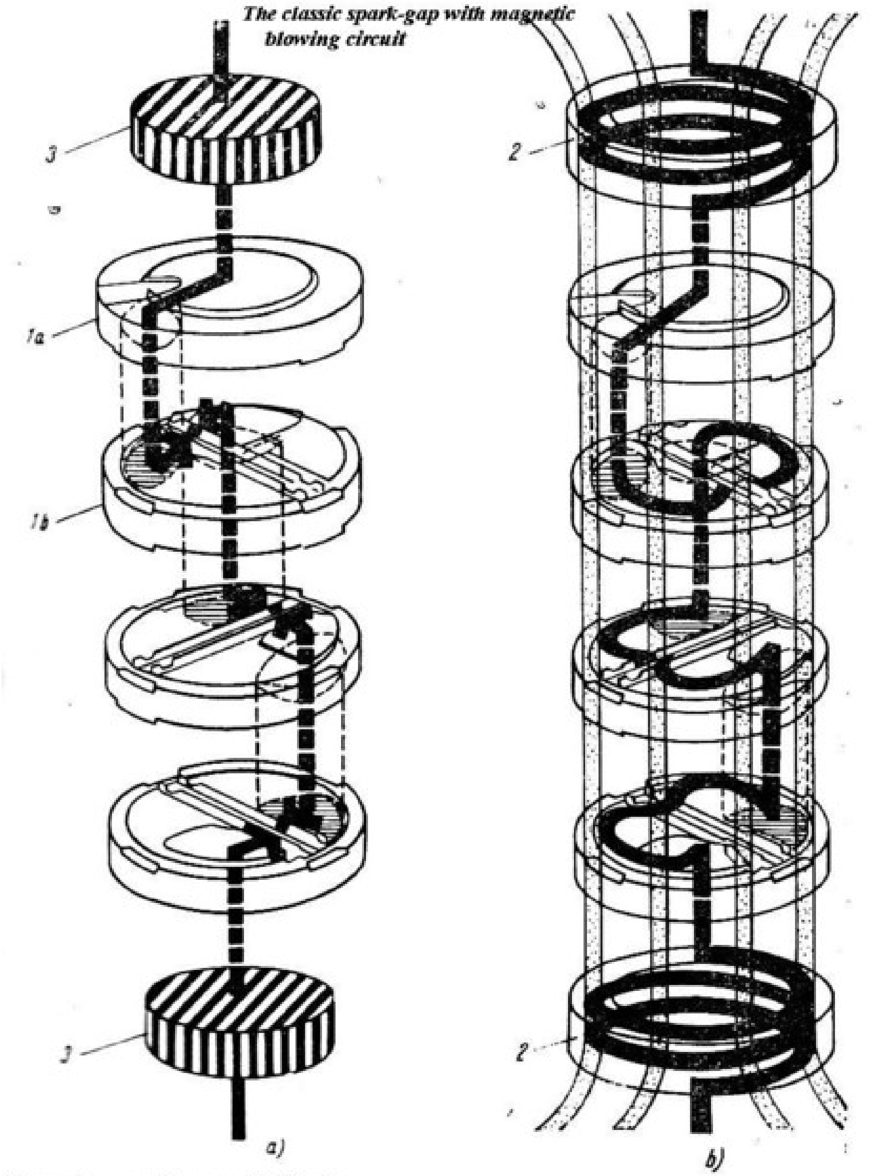
This boot will continue until the disposal of electrical current atmosphere is evident by the one or more table lamps L of resistance shown in Figure 5.

Once the lights illuminate it is advisable to charge the batteries to boot. Natural flow and constant currents will be captured by the regulators , Figure 3; they will regularize in tension and in amperage and then directed to use in table lamps.

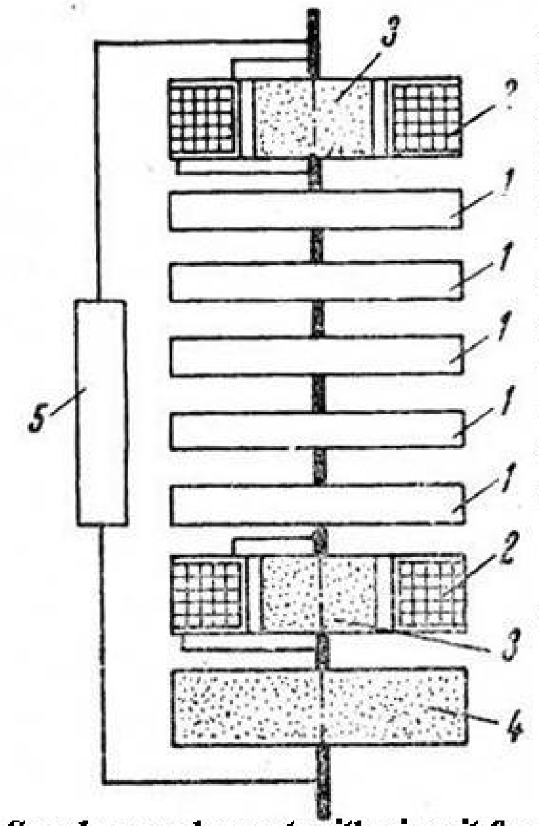
It has been said above that regulators R, etc., are intended and designed to automatically eliminate earth surge currents capture and abnormal currents that cannot yet be level but that these regulators could be replaced by devices with the same function.

There is therefore no need to describe in detail and especially the claims. We only specify that these regulators must be proper protection for the purposes described above.

The classic spark-gap with magnetic blowing circuit



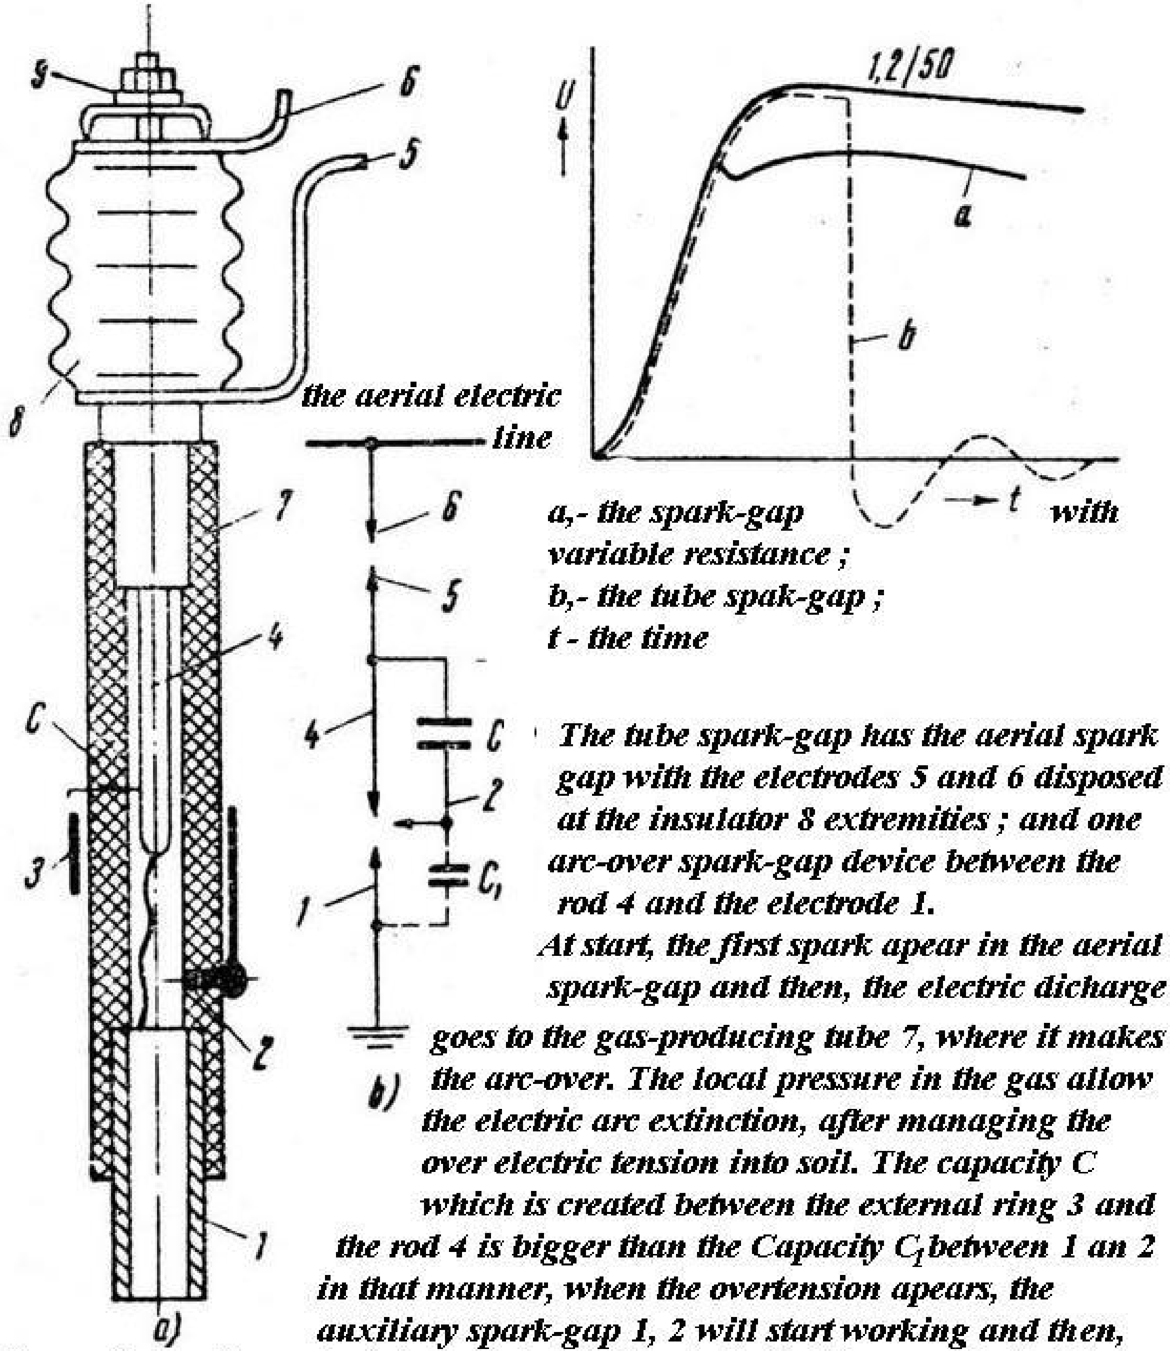
The spark-gap with magnetic blowing :
a,- the initial stage ; the impulse current send in soil through the shunt-resistences 3, because the coils 2 have an impedance too big for the impulse of 10/20 µs ;
the spark-gap 1 has two elements disc-shaped 1a and 1b, the inferior disc have one electrode and the upper disc the other electrode of the spark-gap circuit.
b,- the second stage ; the accompanying current discharge - after the impulse current ;
this accompanying current pass through the coils 2 which produce the magnetic field with the role to extend the electric arc into the slit between insulator discs 1a and 1b ; the thickness of this slit is smaller and smaller in accord with the extension of the electric arc, in this manner producing the magnifing of its electric resistance and finally, the electric arc extinction.



1,- the spark-gap individual devices which work in the manner to extend the electric arc of the accompanying electric current ;
2,- the coils which produce the magnetic field for the magnetic blowing ;
3,- the electric shunt-resistances in parallel connection on the blowing coils, with the role of reducing the current inside this coils
4,- the disc with unlinear resistance ;
5,- electrical resistance for the homogenous distribution of the electric field in all the elements of the spark-gap.

In Jules Guillot scheme, that kind of device could be used for leading the current.

Spark-gap element with circuit for the magnetic blowing of the electric fascicle



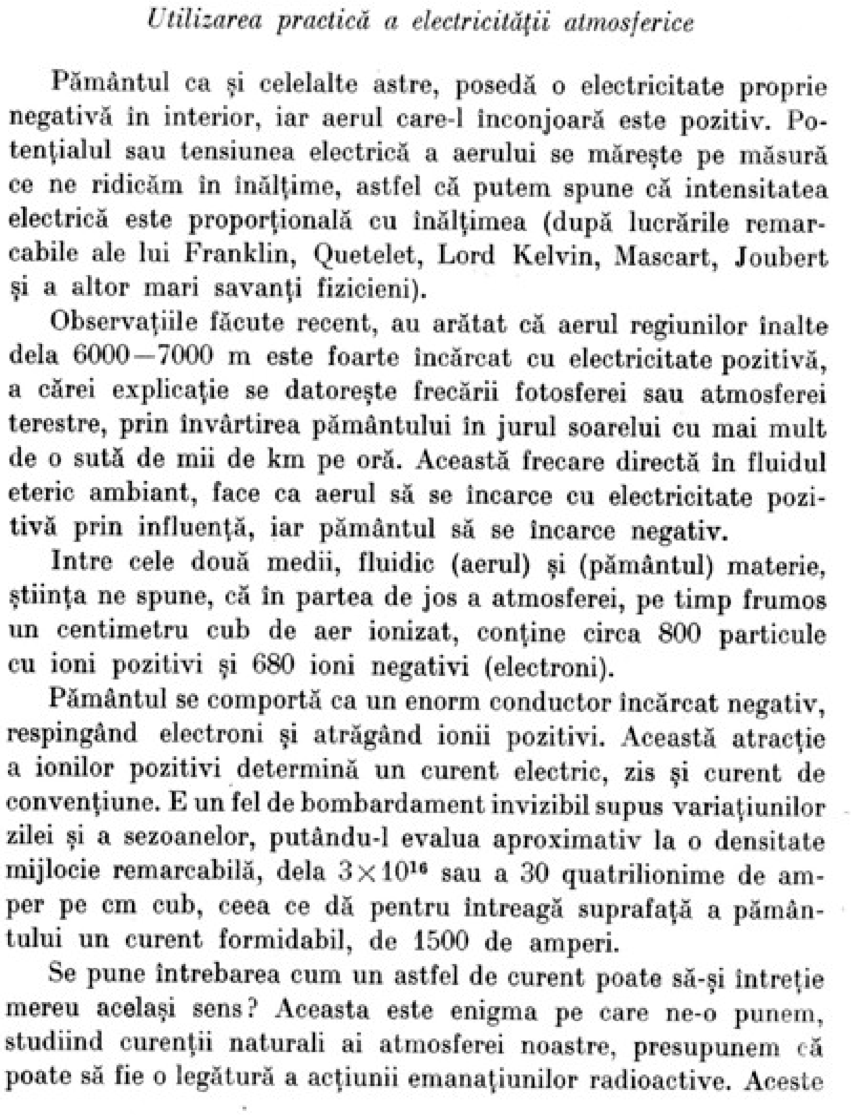
a,- the spark-gap with variable resistance ;
b,- the tube spak-gap ;
t - the time

The tube spark-gap has the aerial spark gap with the electrodes 5 and 6 disposed at the insulator 8 extremities ; and one arc-over spark-gap device between the rod 4 and the electrode 1.

At start, the first spark apear in the aerial spark-gap and then, the electric dicharge goes to the gas-producing tube 7, where it makes the arc-over. The local pressure in the gas allow the electric arc extinction, after managing the over electric tension into soil. The capacity C which is created between the external ring 3 and the rod 4 is bigger than the Capacity C_1 between 1 an 2 in that manner, when the overtension apears, the auxiliary spark-gap 1, 2 will start working and then, the main spark-gap 1, 4. In this circuit, the electrode 9 is connected at the aerial electric line and the electrode 1 at the Earth.

In the image above, it is an classic tube spark-gap used for the protection of aerial electric cables. The atmospheric electricity is discharged in soil and lost... The Guillot's inventions used that kind of devices for leading and absorbing of the atmospheric electricity.

DARIDA, Gillbert : "Practical Utilization of Atmospheric Electricity";
(in *The Invention Encyclopedia,* pp. 204-207 ; 1930, Geo. Constantinescu, Ed.) --



Utilizarea practică a electricității atmosferice

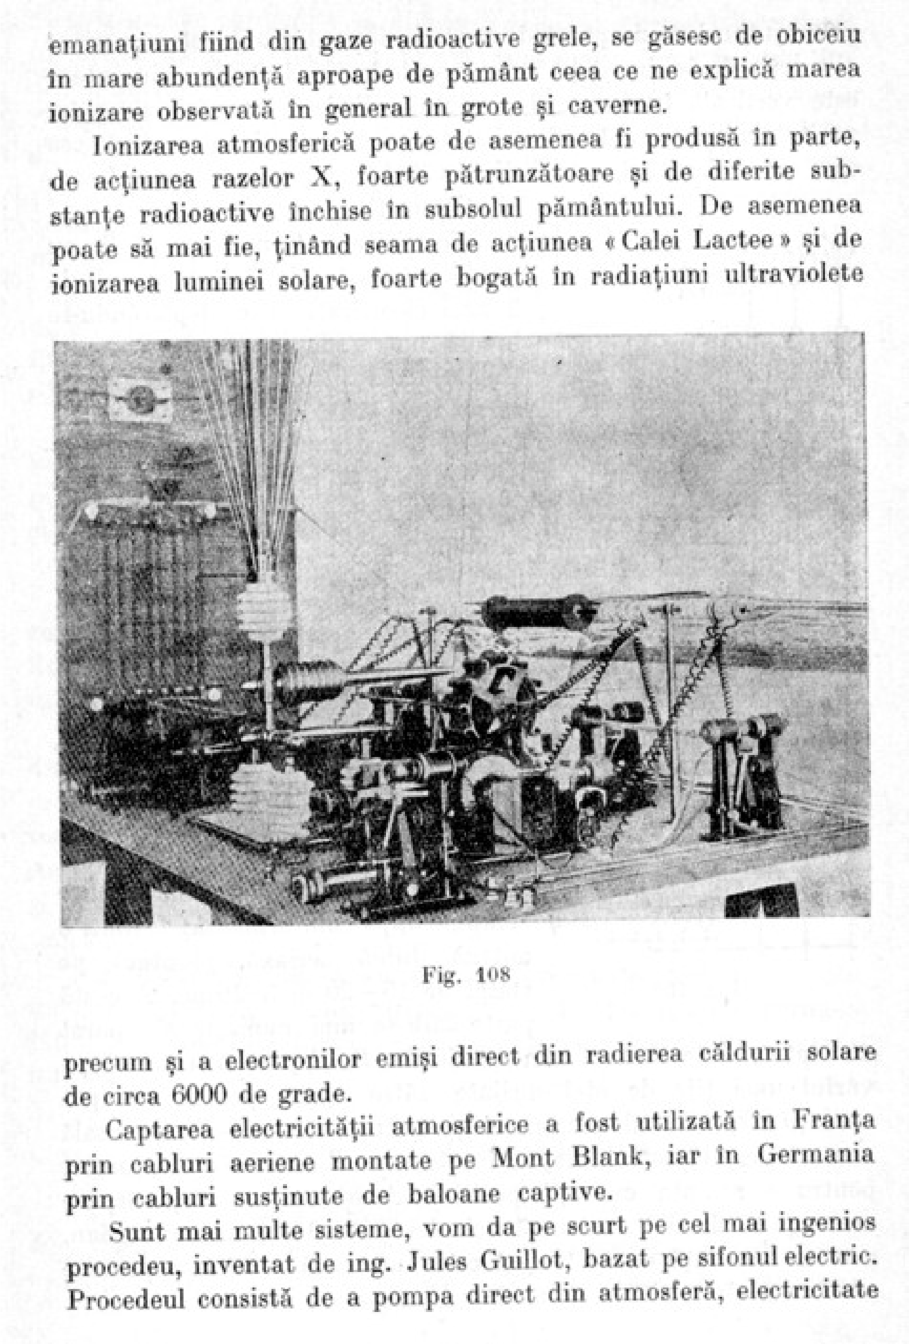
Pământul ca și celelalte astre, posedă o electricitate proprie negativă în interior, iar aerul care-l înconjoară este pozitiv. Potențialul sau tensiunea electrică a aerului se mărește pe măsură ce ne ridicăm în înălțime, astfel că putem spune că intensitatea electrică este proporțională cu înălțimea (după lucrările remarcabile ale lui Franklin, Quetelet, Lord Kelvin, Mascart, Joubert și a altor mari savanți fizicieni).

Observațiile făcute recent, au arătat că aerul regiunilor înalte dela 6000—7000 m este foarte încărcat cu electricitate pozitivă, a cărei explicație se datorește frecării fotosferei sau atmosferei terestre, prin învârtirea pământului în jurul soarelui cu mai mult de o sută de mii de km pe oră. Această frecare directă în fluidul eteric ambiant, face ca aerul să se încarce cu electricitate pozitivă prin influență, iar pământul să se încarce negativ.

Intre cele două medii, fluidic (aerul) și (pământul) materie, știința ne spune, că în partea de jos a atmosferei, pe timp frumos un centimetru cub de aer ionizat, conține circa 800 particule cu ioni pozitivi și 680 ioni negativi (electroni).

Pământul se comportă ca un enorm conductor încărcat negativ, respingând electroni și atrăgând ionii pozitivi. Această atracție a ionilor pozitivi determină un curent electric, zis și curent de convențiune. E un fel de bombardament invizibil supus variațiunilor zilei și a sezoanelor, putându-l evalua aproximativ la o densitate mijlocie remarcabilă, dela 3×10^{16} sau a 30 quatrilionime de amper pe cm cub, ceea ce dă pentru întreagă suprafață a pământului un curent formidabil, de 1500 de amperi.

Se pune întrebarea cum un astfel de curent poate să-și întreție mereu același sens? Aceasta este enigma pe care ne-o punem, studiind curenții naturali ai atmosferei noastre, presupunem că poate să fie o legătură a acțiunii emanațiunilor radioactive. Aceste



emanaţiuni fiind din gaze radioactive grele, se găsesc de obiceiu în mare abundenţă aproape de pământ ceea ce ne explică marea ionizare observată în general în grote şi caverne.

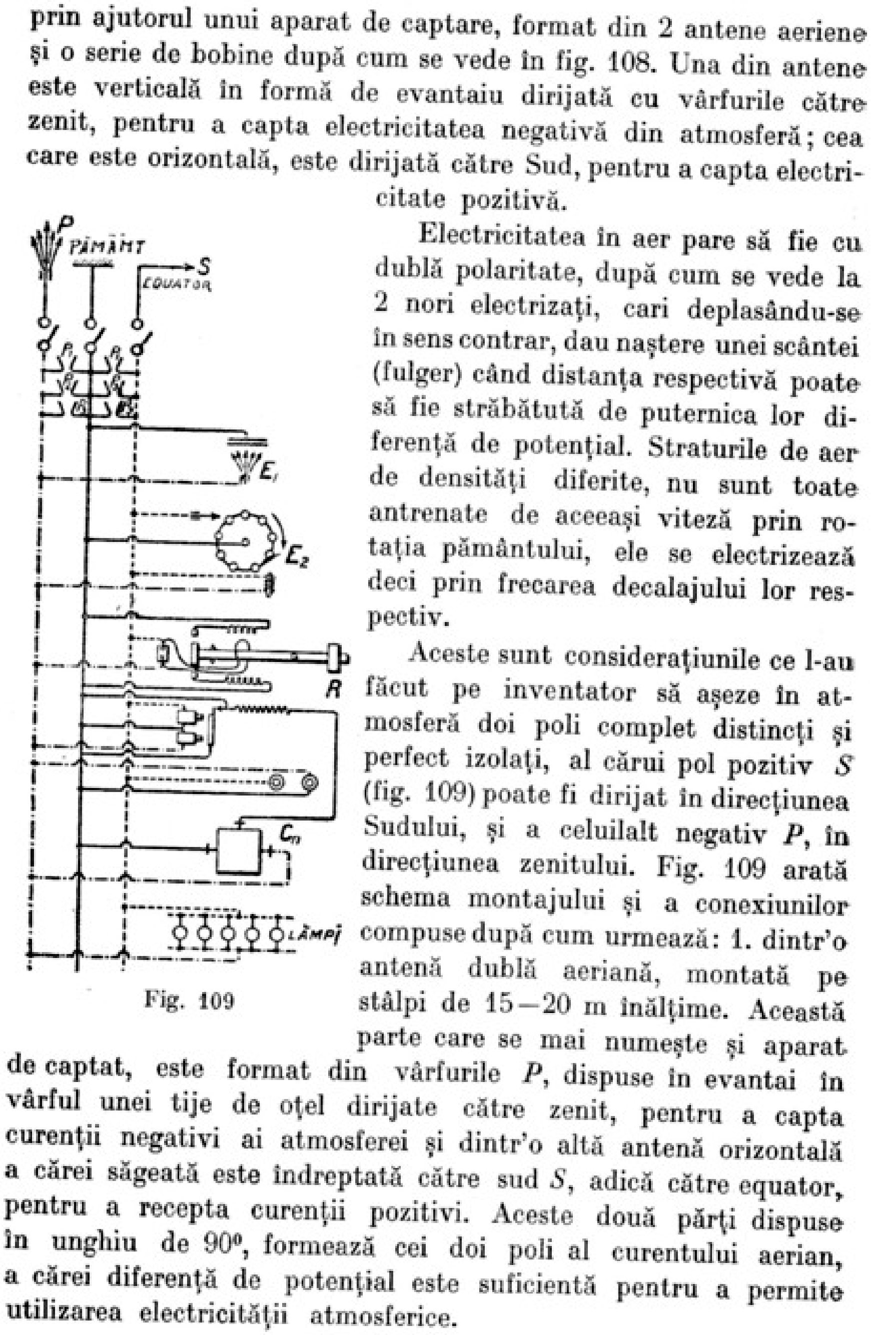
Ionizarea atmosferică poate de asemenea fi produsă în parte, de acţiunea razelor X, foarte pătrunzătoare şi de diferite substanţe radioactive închise în subsolul pământului. De asemenea poate să mai fie, ţinând seama de acţiunea «Calei Lactee» şi de ionizarea luminei solare, foarte bogată în radiaţiuni ultraviolete

Fig. 108

precum şi a electronilor emişi direct din radierea căldurii solare de circa 6000 de grade.

Captarea electricităţii atmosferice a fost utilizată în Franţa prin cabluri aeriene montate pe Mont Blank, iar în Germania prin cabluri susţinute de baloane captive.

Sunt mai multe sisteme, vom da pe scurt pe cel mai ingenios procedeu, inventat de ing. Jules Guillot, bazat pe sifonul electric. Procedeul consistă de a pompa direct din atmosferă, electricitate



P
PĂMÂNT
S
EQUATOR
E₁
E₂
R
Cₙ
LĂMPI

prin ajutorul unui aparat de captare, format din 2 antene aeriene şi o serie de bobine după cum se vede în fig. 108. Una din antene este verticală în formă de evantaiu dirijată cu vârfurile către zenit, pentru a capta electricitatea negativă din atmosferă; cea care este orizontală, este dirijată către Sud, pentru a capta electricitate pozitivă.

Electricitatea în aer pare să fie cu dublă polaritate, după cum se vede la 2 nori electrizaţi, cari deplasându-se în sens contrar, dau naştere unei scântei (fulger) când distanţa respectivă poate să fie străbătută de puternica lor diferenţă de potenţial. Straturile de aer de densităţi diferite, nu sunt toate antrenate de aceeaşi viteză prin rotaţia pământului, ele se electrizează deci prin frecarea decalajului lor respectiv.

Aceste sunt consideraţiunile ce l-au făcut pe inventator să aşeze în atmosferă doi poli complet distincţi şi perfect izolaţi, al cărui pol pozitiv *S* (fig. 109) poate fi dirijat în direcţiunea Sudului, şi a celuilalt negativ *P*, în direcţiunea zenitului. Fig. 109 arată schema montajului şi a conexiunilor compuse după cum urmează: 1. dintr'o antenă dublă aeriană, montată pe stâlpi de 15—20 m înălţime. Această parte care se mai numeşte şi aparat de captat, este format din vârfurile *P*, dispuse în evantai în vârful unei tije de oţel dirijate către zenit, pentru a capta curenţii negativi ai atmosferei şi dintr'o altă antenă orizontală a cărei săgeată este îndreptată către sud *S*, adică către equator, pentru a recepta curenţii pozitivi. Aceste două părţi dispuse în unghiu de 90°, formează cei doi poli al curentului aerian, a cărei diferenţă de potenţial este suficientă pentru a permite utilizarea electricităţii atmosferice.

Fig. 109

French Patent # 551,882

Appareil Capteur de Courants Electriques dans L'Atmosphere

BREVET D'INVENTION.

XII. — Instruments de précision, électricité.

5. — Production de l'électricité, moteurs électriques.

N° 551.882

Appareil capteur de courants électriques dans l'atmosphère.

M. Jules GUILLOT résidant en France (Tarn-et-Garonne).

Demandé le 27 septembre 1921, à 15h 20m, à Paris.
Délivré le 15 janvier 1923. — Publié le 16 avril 1923.

[Brevet d'invention dont la délivrance a été ajournée en exécution de l'art. 11 § 7 de la loi du 5 juillet 1844 modifiée par la loi du 7 avril 1902.]

Considérant le globe terrestre comme l'induit d'une dynamo, dont l'éther supraterrestre est l'inducteur, des courants électriques circulent dans l'intervalle c'est-à-dire dans la couche atmosphérique; l'inventeur capte au moyen de l'appareil décrit ci-dessous deux de ces courants parfaitement distincts et élimine les autres.

L'appareil comprend :

1° Le capteur aérien; 2° une série de parafoudres; 3° les régulateurs; 4° un tableau de résistances; 5° les aspirateurs; 6° les témoins.

1° Le capteur aérien monté sur un poteau est composé d'une pointe d'acier aimanté fixée par scellement sur un isolateur porcelaine et cerclée à sa base par une bague de bronze sur laquelle sont vissées 32 aiguilles de fer doux, le tout formant l'antenne d'un pôle. A côté et isolé de la première, formant le 2e pôle, est fixée une pointe d'acier aimanté dans la position horizontale et dirigée vers le sud dont la base coudée à 45° est scellée sur un isolateur porcelaine. Cette pointe est également cerclée d'une bague de cuivre à encoches fig. 1.

2° Une série de 6 parafoudres à cornes entre chaque pôle et la terre et à écartements variés.

3° Un premier régulateur formé d'un appareil absolument semblable au capteur aérien, mais ayant les deux pôles superposés, et, opposé à la pointe verticale, un disque de cuivre relié à la terre. Opposé à la pointe horizontale, une roue à jante d'étain sur laquelle sont soudés alternativement 16 tubes composés eux-mêmes de deux métaux soudés : cuivre-plomb et fer-plomb. Cette roue est reliée à la terre par son pivot fig. 2.

Un deuxième régulateur formé d'appareils à déclanchement automatique au nombre de 3 par pôles et deux basculateurs également par pôles.

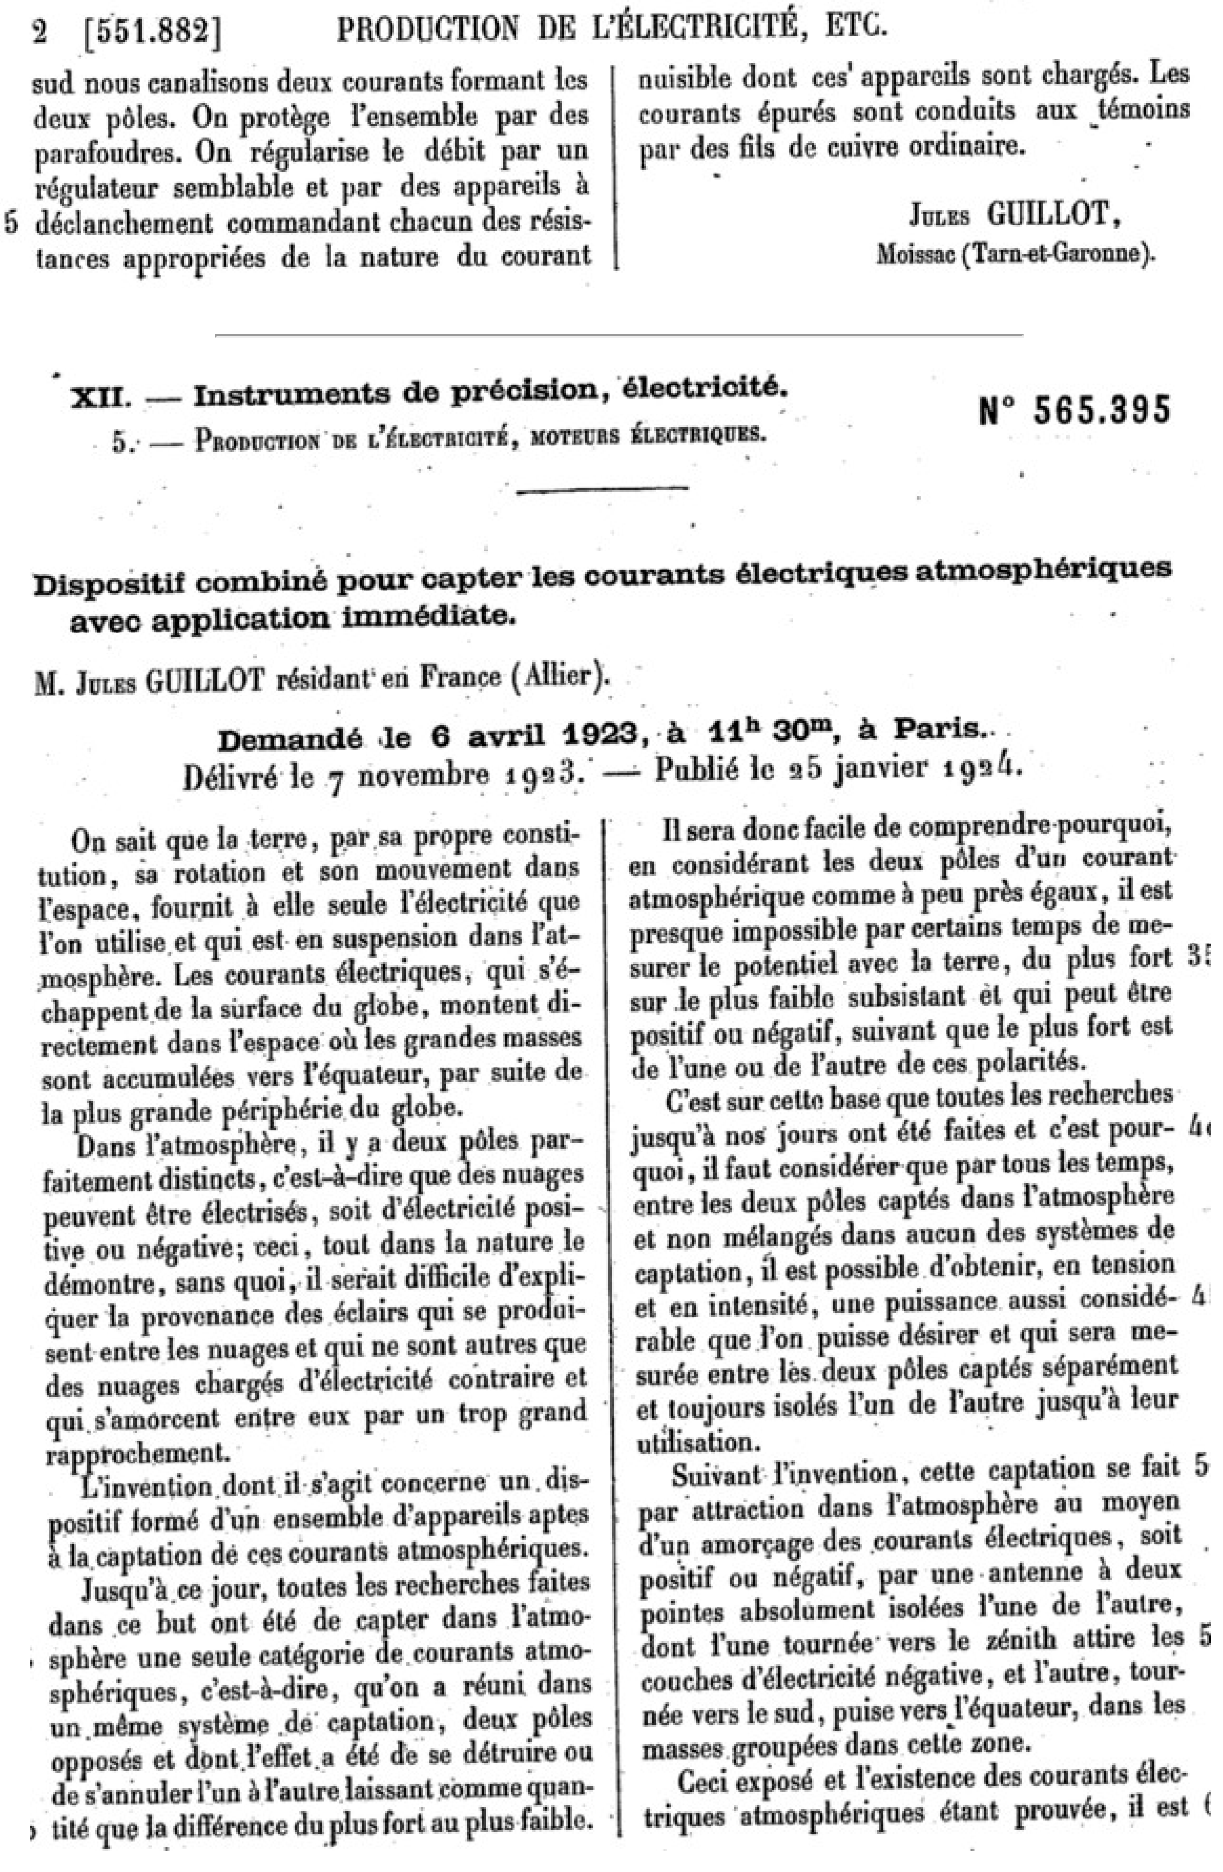
4° Un tableau de résistances composé de fils de maillechort en boudins de différentes sections, de tubes en verre contenant des poussières de cuivre, du charbon de cornue et de la fleur de soufre.

5° Les aspirateurs composés d'une boîte en bois sur chaque pôle, contenant un vase de porcelaine dans lequel par couches superposées et isolées au mica est placé du mercure, de l'étain, du charbon, du cuivre et du soufre, le tout traversé par une tige de cuivre.

6° Les témoins composés de lampes à incandescence ordinaires.

RÉSUMÉ.

Par la pointe au zénith et par la pointe au



sud nous canalisons deux courants formant les deux pôles. On protège l'ensemble par des parafoudres. On régularise le débit par un régulateur semblable et par des appareils à déclanchement commandant chacun des résistances appropriées de la nature du courant nuisible dont ces appareils sont chargés. Les courants épurés sont conduits aux témoins par des fils de cuivre ordinaire.

Jules GUILLOT,
Moissac (Tarn-et-Garonne).

XII. — Instruments de précision, électricité.

5. — Production de l'électricité, moteurs électriques.

N° 565.395

Dispositif combiné pour capter les courants électriques atmosphériques avec application immédiate.

M. Jules GUILLOT résidant en France (Allier).

Demandé le 6 avril 1923, à 11h 30m, à Paris.
Délivré le 7 novembre 1923. — Publié le 25 janvier 1924.

On sait que la terre, par sa propre constitution, sa rotation et son mouvement dans l'espace, fournit à elle seule l'électricité que l'on utilise et qui est en suspension dans l'atmosphère. Les courants électriques, qui s'échappent de la surface du globe, montent directement dans l'espace où les grandes masses sont accumulées vers l'équateur, par suite de la plus grande périphérie du globe.

Dans l'atmosphère, il y a deux pôles parfaitement distincts, c'est-à-dire que des nuages peuvent être électrisés, soit d'électricité positive ou négative; ceci, tout dans la nature le démontre, sans quoi, il serait difficile d'expliquer la provenance des éclairs qui se produisent entre les nuages et qui ne sont autres que des nuages chargés d'électricité contraire et qui s'amorcent entre eux par un trop grand rapprochement.

L'invention dont il s'agit concerne un dispositif formé d'un ensemble d'appareils aptes à la captation de ces courants atmosphériques.

Jusqu'à ce jour, toutes les recherches faites dans ce but ont été de capter dans l'atmosphère une seule catégorie de courants atmosphériques, c'est-à-dire, qu'on a réuni dans un même système de captation, deux pôles opposés et dont l'effet a été de se détruire ou de s'annuler l'un à l'autre laissant comme quantité que la différence du plus fort au plus faible.

Il sera donc facile de comprendre pourquoi, en considérant les deux pôles d'un courant atmosphérique comme à peu près égaux, il est presque impossible par certains temps de mesurer le potentiel avec la terre, du plus fort sur le plus faible subsistant et qui peut être positif ou négatif, suivant que le plus fort est de l'une ou de l'autre de ces polarités.

C'est sur cette base que toutes les recherches jusqu'à nos jours ont été faites et c'est pourquoi, il faut considérer que par tous les temps, entre les deux pôles captés dans l'atmosphère et non mélangés dans aucun des systèmes de captation, il est possible d'obtenir, en tension et en intensité, une puissance aussi considérable que l'on puisse désirer et qui sera mesurée entre les deux pôles captés séparément et toujours isolés l'un de l'autre jusqu'à leur utilisation.

Suivant l'invention, cette captation se fait par attraction dans l'atmosphère au moyen d'un amorçage des courants électriques, soit positif ou négatif, par une antenne à deux pointes absolument isolées l'une de l'autre, dont l'une tournée vers le zénith attire les couches d'électricité négative, et l'autre, tournée vers le sud, puise vers l'équateur, dans les masses groupées dans cette zone.

Ceci exposé et l'existence des courants électriques atmosphériques étant prouvée, il est

possible de les capter à la condition de disposer d'appareils spéciaux étudiés surtout pour jouer le rôle de régulateurs, attendu que la difficulté persistante rencontrée jusqu'alors pour réaliser la captation incombe aux grandes variations de tensions sous lesquelles les courants atmosphériques se présentent dans l'espace, pour chacun des pôles, et dont l'écoulement dans un poste de captation serait inévitablement funeste.

Le présent brevet sous sa forme de présentation doit donc couvrir, non pas le ou les dispositifs régulateurs qui sont prévus dans le système, car ils peuvent être conçus d'une façon toute différente et donner le même résultat, mais sur l'application raisonnée et le groupement d'appareils fonctionnant automatiquement et intervenant chacun comme relais d'influence variable pour limiter la tension des courants captés dans l'atmosphère à celle choisie pour utilisation.

Ces appareils ont un rôle assez connexe avec celui de trop-pleins sur un réservoir qui acheminent à l'extérieur l'excès de liquide; ici ces régulateurs détournent l'excès de tension des courants à la terre.

On peut encore assimiler ces régulateurs à des filtres car ils ont pour but de détourner du poste d'utilisation, des courants qui ne sont pas encore de nature connue mais que pour simplicité on appellera courants parasites ou anormaux.

Le brevet portera aussi sur le système de régulation des courants, appliqué à chacun des pôles, car il est reconnu que la forme et la tension des courants aux deux pôles ne sont pas équivalentes.

Le mode de captation par antenne spéciale à deux pointes orientées dans l'atmosphère, comme il sera indiqué ci-après, avec amorçage préalable pour l'écoulement des courants atmosphériques est aussi d'une grande importance.

Enfin la réception des courants atmosphériques se fait à l'endroit même de l'installation du poste; celui-ci peut être prévu en un lieu quelconque sans nécessiter d'altitude particulière, comme cela a été tenté dans des essais préconçus.

Sur les dessins ci-annexés auxquels on se réfère

La fig. 1 représente en élévation et en coupe partielle l'antenne seule, à deux pointes, surmontant un poteau d'élévation;

La fig. 2 est le plan de l'une des pointes, celle horizontale:

La fig. 3 montre schématiquement le tableau sur lequel sont montés les divers appareils ou accessoires qui jouent le rôle de régulateurs des tensions de courants.

La fig. 4 est un schéma de parafoudre, et

La fig. 5 un tableau de résistances.

Le dispositif nécessaire à la captation des courants atmosphériques est formé comme suit :

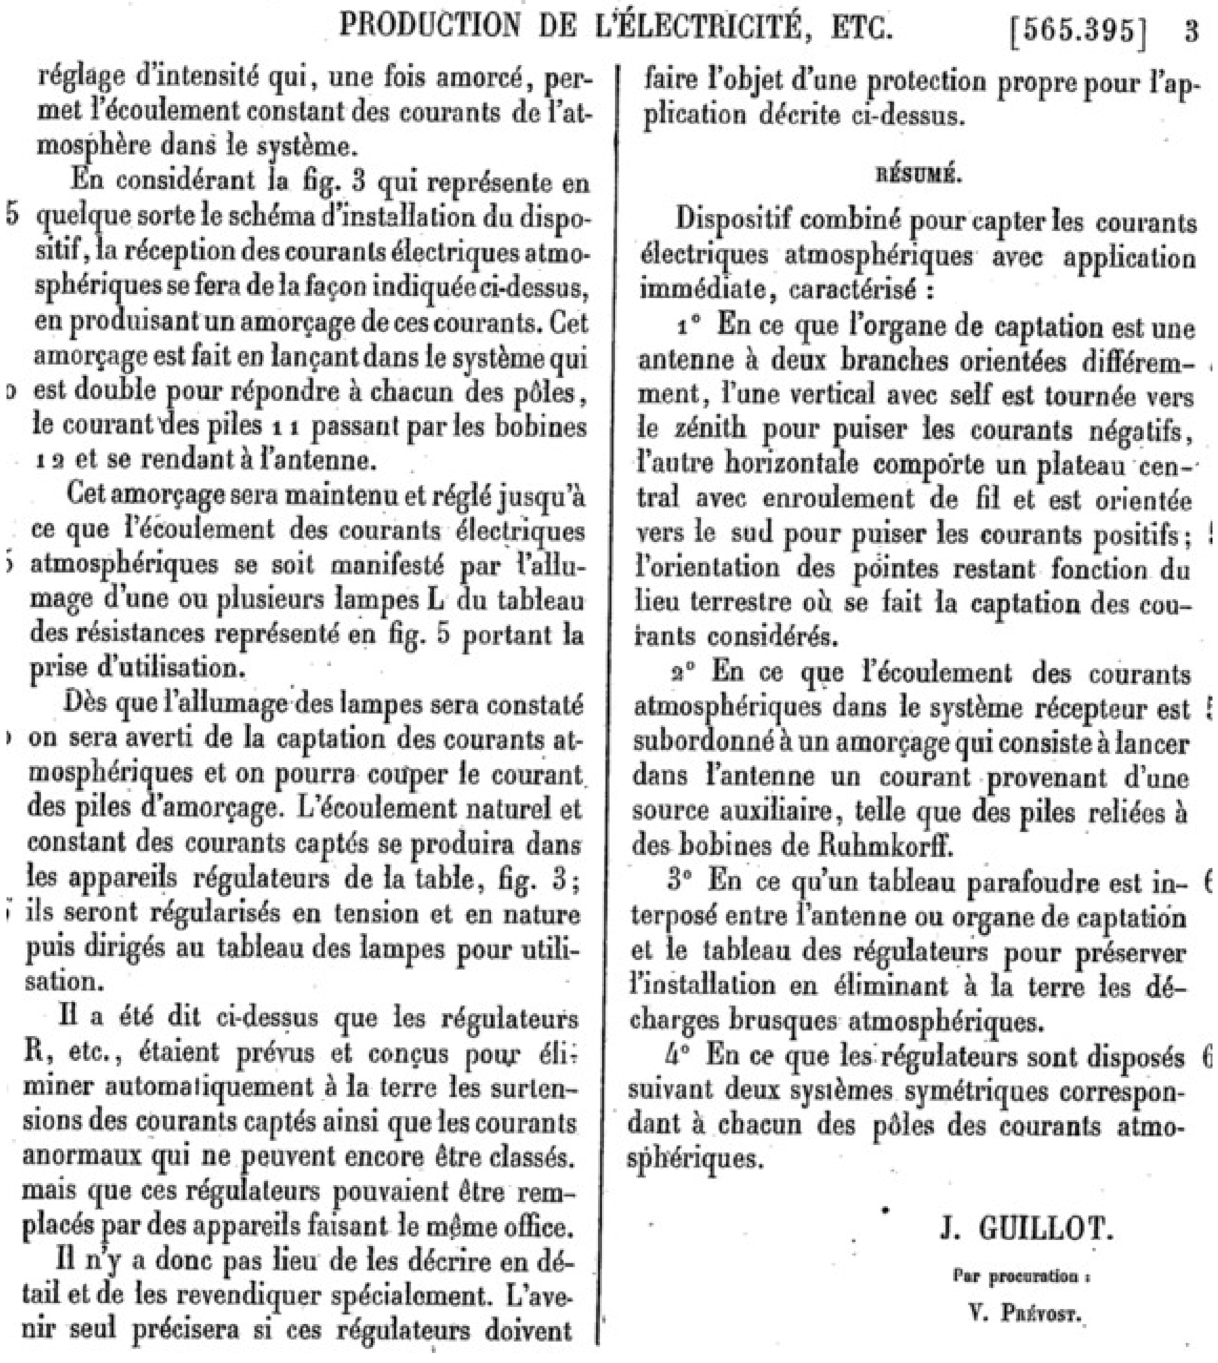
1° D'une antenne, fig. 1, formée de deux pointes dont l'une 1 est en acier, supportée par une bague de bronze 2 entourée d'une spirale 3 formant self; cette pointe est tournée vers le zénith pour attirer les couches d'électricité négative; l'autre pointe 4 comporte un cadre 5 de huit branches supportant des spirales de cuivre 6 et est tournée vers le sud pour puiser vers l'équateur dans les masses groupées dans cette zone. Pour l'utilisation de cette antenne il suffira qu'elle soit portée par un mât ou poteau de hauteur un peu supérieure à celle des habitations environnantes.

2° D'un tableau de parafoudre, fig. 4, formé de cornes de cuivre 7 servant à absorber les tros grosses décharges atmosphériques que par certains temps, il serait dangereux de laisser circuler dans les appareils régulateurs.

3° D'une table de deux systèmes symétriques de régulateurs, fig. 3, un pour chaque pôle, qui permet d'obtenir une régularisation assez grande dans les tensions des courants en absorbant automatiquement les surtensions dépassant la tension choisie pour l'utilisation désirée. Ces régulateurs sont représentés sur le dessin par les références R, R^1, R^2, R^3, R^4.

4° D'un tableau de résistance en communication avec les régulateurs, ces résistances sont formées de spirales de maillechor 8, de tubes 9 de verre remplis de poussière fine de charbon de cornue, de poudre d'aluminium, de soufre et de poussière fine de cuivre; enfin, deux appareils spéciaux 10 formant transformateurs et constitués de couches de métaux absorbant certains courants nuisibles ou anormaux.

5° D'une source auxiliaire d'énergie formée de piles 11 et de bobines Ruhmkorff 12 permettant d'obtenir dans l'antenne une attraction suffisante au moyen d'un dispositif de



réglage d'intensité qui, une fois amorcé, permet l'écoulement constant des courants de l'atmosphère dans le système.

En considérant la fig. 3 qui représente en quelque sorte le schéma d'installation du dispositif, la réception des courants électriques atmosphériques se fera de la façon indiquée ci-dessus, en produisant un amorçage de ces courants. Cet amorçage est fait en lançant dans le système qui est double pour répondre à chacun des pôles, le courant des piles 11 passant par les bobines 12 et se rendant à l'antenne.

Cet amorçage sera maintenu et réglé jusqu'à ce que l'écoulement des courants électriques atmosphériques se soit manifesté par l'allumage d'une ou plusieurs lampes L du tableau des résistances représenté en fig. 5 portant la prise d'utilisation.

Dès que l'allumage des lampes sera constaté on sera averti de la captation des courants atmosphériques et on pourra couper le courant des piles d'amorçage. L'écoulement naturel et constant des courants captés se produira dans les appareils régulateurs de la table, fig. 3; ils seront régularisés en tension et en nature puis dirigés au tableau des lampes pour utilisation.

Il a été dit ci-dessus que les régulateurs R, etc., étaient prévus et conçus pour éliminer automatiquement à la terre les surtensions des courants captés ainsi que les courants anormaux qui ne peuvent encore être classés. mais que ces régulateurs pouvaient être remplacés par des appareils faisant le même office.

Il n'y a donc pas lieu de les décrire en détail et de les revendiquer spécialement. L'avenir seul précisera si ces régulateurs doivent faire l'objet d'une protection propre pour l'application décrite ci-dessus.

RÉSUMÉ.

Dispositif combiné pour capter les courants électriques atmosphériques avec application immédiate, caractérisé :

1° En ce que l'organe de captation est une antenne à deux branches orientées différemment, l'une vertical avec self est tournée vers le zénith pour puiser les courants négatifs, l'autre horizontale comporte un plateau central avec enroulement de fil et est orientée vers le sud pour puiser les courants positifs; l'orientation des pointes restant fonction du lieu terrestre où se fait la captation des courants considérés.

2° En ce que l'écoulement des courants atmosphériques dans le système récepteur est subordonné à un amorçage qui consiste à lancer dans l'antenne un courant provenant d'une source auxiliaire, telle que des piles reliées à des bobines de Ruhmkorff.

3° En ce qu'un tableau parafoudre est interposé entre l'antenne ou organe de captation et le tableau des régulateurs pour préserver l'installation en éliminant à la terre les décharges brusques atmosphériques.

4° En ce que les régulateurs sont disposés suivant deux systèmes symétriques correspondant à chacun des pôles des courants atmosphériques.

(57) **ABSTRACT**

A mechanism to tap an electrical source which uses an aircraft (preferably a lighter than air balloon) tethered by a conductive line. The conductive line is extended/withdrawn by a winch motor to adjust the altitude of the aircraft. The conductive line is isolated from the ground and an electrical conductor is connected to the conductive line and to an electrical load. In this manner, static electricity generated in the atmosphere is gathered for use.

ATMOSPHERIC ELECTRICAL GENERATOR

BACKGROUND OF THE INVENTION

This invention relates to the production of electrical energy and more particularly to the production of electrical energy from the atmosphere.

Everyone is familiar with Benjamin Franklin's kite experiment of 1752. Using a kite whose string had become wet, negative charges from the passing clouds flowed into the string, down to the suspended key, and then into a Leyden jar via a thin metal wire. Franklin was protected by a dry silk string; but, when Franklin's knuckle came too close to the key, he received a strong shock. Fortunately, Benjamin Franklin was not killed, others who tried this same experiment were not so lucky.

Since then, the formation of lightning has remained something of a mystery. Lightning bolts are triggered when a negatively charged cloud base induces a positive charge from the ground, thereby forming a "pathway" for the discharge of the collected electrical energy.

Lightning travels up to 60,000 miles per hour with a flash that is brighter than ten million 100-watt lightbulbs. This wattage is as much power as is produced by all of the electricity plants in the United States and with a voltage of up to 300 million volts.

It is this very fact, the power within lightning is immense, that has prevented any successful collection of the electrical energy from lightning. The electricity in lightning is far too extreme for current technology to harness.

While lightning has attracted a energy starved industrial world, no one has developed any technique to harness this naturally occurring electrical source.

It is clear there is a continuing need for an electrical source other than carbon-based fuels and that the naturally occurring electricity in the atmosphere is being ignored.

SUMMARY OF THE INVENTION

The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to garner electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and avoids lightning.

Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal activity, static electricity is being generated.

The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

The mechanism of this invention utilizes an aircraft such as a lighter than air balloon. While the preferred embodiment uses a foil balloon, a variety of other aircraft are obvious to those of ordinary skill in the art, including, but not limited to: gliders, rubber balloons (such as weather balloons), biaxially-oriented polyethylene terephthalate polyester film balloons, and latex balloons.

Within this discussion, the balloon is referenced, but, the invention is not intended to be limited solely to balloons.

The balloon is sent aloft and is tethered by a conductive line. In this context, the conductive line may be any obvious to those of ordinary skill in the art. For the preferred embodiment, the conductive line is a generically referred to as a "poly-rope" and is commercially available through a variety of sources. A suitable conductive line is described in U.S. Pat. No. 5,203,542, entitled "Apparatus for Improved Electric Fence Wire Construction for use with Intensive Grazing" issued Apr. 20, 1993, to Coley, et al. and incorporated hereinto by reference.

The conductive line is played out of a winch to control the altitude of the balloon. The motor controlling the winch is able to reverse direction to both extend and withdraw the conductive line which is wrapped around a spool on the winch. The winch/spool combination are part of a base unit.

In some embodiments of the invention, the spool is constructed of rubber so as to insulate the conductive line from the winch assembly. In this embodiment, only the conductive line is charged by the atmospheric static electricity while the winch remains neutral.

In yet another embodiment, the winch/spool are part of a base unit which is itself isolated from the ground by an insulator. In this embodiment, the entire base unit is charged by the atmospheric static electricity.

A conductor, such as an insulated wire, is electrically connected to the conductive line. In one embodiment, where the conductive line is electrically isolated from the spool and winch motor, the conductor is connected to the conductive line. In the embodiment where the conductive line is electrically connected to the base unit, then the conductor is connected anywhere on a metallic base unit.

The other end of the conductor is connected to a load. The load in this case can be any of a variety of electrical loads well known to those of ordinary skill in art, including, but not limited to a motor, a battery system, or the electrical grid for the system.

In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale.

A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor.

In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention.

The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

This preset range is established either in the base programming of the controller or is established by an operator of the system.

As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism operates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

The invention, together with various embodiments thereof will be more fully explained by the following description of the accompanying drawings.

DRAWINGS IN BRIEF

FIG. **1** diagrams the preferred embodiment of the invention.

FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

DRAWINGS IN DETAIL

FIG. **1** diagrams the preferred embodiment of the invention.

Balloon **10** is an aircraft which, in this illustration, is a lighter than air balloon. Wings **10**A, extending from the body of balloon **10**, provide additional lift in air flow **18**. Tail **10**B helps to stabilize balloon **10**.

Balloon **10** is tethered to the ground via conductive line **12**. As noted earlier, a variety of configurations and materials are available to serve as conductive line **12**. In this illustration, a poly-wire is used Poly-wire is commercially available through a variety of vendors, including, but not limited to: Jeffers Livestock and Zareba Systems, Inc, of Ellendale, Minn.

In this embodiment, located proximate to balloon **10**, is an electrical collection enhancement lead **11** which assists in the collection of the static electrical charge in the atmosphere. Electrical collection enhancement lead **11** is configured to attract the static charge and conduct the charge into the conductive line **12**.

The electricity flows down the conductive line into spool **13**, where the conductive line **12** is collected and either withdrawn or dispensed through operation of winch motor **14**.

Winch motor **14** and spool **13** are mounted onto base unit **16** which is electrically isolated from ground **7** using insulator **17**. Note, in this embodiment of the invention, when electricity is being collected from the atmosphere, the entire base unit **16** becomes charged. In another embodiment of the invention, spool **13** is constructed of rubber, thereby preventing base unit **16** from becoming charged, thereby restricting the charging from the atmosphere to only conductive line **12**.

In this embodiment, conductor **6** is connected to base unit **16** (since the entire base unit **16** is charged and the base unit is metallic) to communicate the electrical current to load **5**. Conductor **6** is ideally an insulated wire.

The electrical current through conductor **6** is measured using sensor **8**.

In the alternative embodiment discussed above, where only the conductive line **12** is charged, then conductor **6** is connected to conductive line **12**.

Controller **15**, located in this embodiment on base unit **16**, operates winch motor **14** in response to signals from sensor **8** (measuring the current being discharged to load **5**) to maintain the current flow within a pre-defined range. As the current flow diminishes, then the conductive line **12** extended from spool **13** to increase the altitude of balloon **10** to that more static charge from the atmosphere is gathered; as the current flow falls exceeds a preset level, conductive line **12** is withdrawn onto spool **13** to decrease the static charge being collected from the atmosphere.

The range of current flow through conductor **6** is ideally set by the program, although some embodiments of the invention permit an operator to establish this range of operation.

In an alternative embodiment, the sensor monitoring conductor **6** monitors the voltage therein.

In the preferred embodiment of the invention, controller **15** is also equipped with a lightning sensor **19**. In this embodiment, when lightning is sensed within a preset range, then substantially all of conductive line **12** is wound onto spool **13** to pull balloon **10** near the ground and protect the entire mechanism from being damaged from a lightning discharge.

In the preferred embodiment, the "safe" distance form lightning is set in the programming of controller **15** and is ideally two miles; other embodiments permit the operator to "safe" distance.

There are a variety of lightning sensors well known to those of ordinary skill in the art, including, but not limited to those described in: U.S. Pat. No. 7,016,785, entitled "Lightning Detection" issued to Makela, et al. on Mar. 21, 2006; U.S. Pat. No. 6,829,911, entitled "Lightning Detection and Prediction Alarm Device" issued to Jones, et al. on Dec. 7, 2004; U.S. Pat. No. 7,200,418, entitled "Detection of Lightning" issued to Karikuranta, et al. on Apr. 3, 2007; and U.S. Pat. No. 6,961,662, entitled "Systems and Methods for Spectral Corrected Lightning Detection" issued to Murphy on Nov. 1, 2005; all of which are incorporated hereinto by reference.

In another embodiment of the invention, controller **15** is not located on base unit **16**, rather it is remote and communicates its control signals to winch motor **14** using radio waves.

FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

Static charges **23** are generated in the atmosphere by agitated air. These static charges are often collected at the bottom of clouds, but exist in other environments as well.

Balloon **21** is extended into this strata of static charges **23** which are then attracted to conductive line **12** to flow to base unit **22** and then onto load **5**.

By increasing or decreasing the altitude of balloon **21** (defined by the length of the extended conductive line **12**), conductive line **12** is selectively exposed to varying densities and levels of the static charge strata, and by extension, the current flow or voltage is increased or decreased.

FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

Once the program starts **30**, the lightning sensor is checked to determine if lightning has occurred within the unsafe range **31**A, if it has, then the balloon is lowered **32**A, and the program continues monitoring the status of lightning until no lightning is detected.

When the lightning status is acceptable, then the current within the conductor is checked to see if the current is within the prescribed range **31**B. If the current is acceptable (within range) the program returns to check the lightning status **31**A; otherwise a determination is made to see if the current is above the prescribed range **31**C.

If the current is above the prescribed range, then the altitude of the balloon is withdrawn a set amount **32**B (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

If the current is below the prescribed range, then the altitude of the balloon is extended a set amount **32**C (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

In this manner of feed-back and minor adjustments in the altitude of the balloon, the current is maintained within a prescribed range which can be handled by the downstream electrical system.

As noted earlier, some embodiments of the invention monitor the voltage instead of the current.

FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **4**A, **4**B, and **4**C illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

Referencing FIG. **4**A, Direct Current In (DC IN) **40** is buffered by a gang of capacitors **41** before being communicated to a DC/AC converter **42**. The DC/AC converter converts the direct current into a an alternating current suitable for placement over an existing electrical grid **43** such as normally found from a power-plant.

Those of ordinary skill in the art readily recognize a variety of DC/AC converters, including, but not limited to: U.S. Pat. No. 7,394,671, entitled “Controller IC, DC-AC Conversion Apparatus, and parallel running system of DC-AC Conversion Apparatuses” issued to Fukumoto, et al. on Jul. 1, 2008; and, U.S. Pat. No. 7,330,366, entitled “DC-AC Converter” issued to Lee, et al. on Feb. 12, 2008; all of which are incorporated hereinto by reference.

FIG. **4**B illustrates an electrical arrangement suitable for use in charging a battery. DC IN **40** is buffered by capacitor bank **41** before entering into a step down transformer **43**. Step down transformer **43** reduces the voltage so that the voltage can safely be introduced into battery **44** which is connected to ground **45** at the battery’s other pole.

Those of ordinary skill in the art readily recognize a variety of batteries which will work in this capacity, including, but not limited to those described in: U.S. Pat. No. 7,378,181, entitled “Electric Storage Battery Construction and Manufacture” issued to Skinlo on May 27, 2008; U.S. Pat. No. 7,388,350, entitled “Battery with Electronic Compartment” issued to Wright on Jun. 17, 2008; U.S. Pat. No. 7,397,220, entitled “Connection Member and Battery Pack” issued to Uchida, et al. on Jul. 8, 2008; and, U.S. Pat. No. 7,375,492, entitled “Inductively Charged Battery Pack” issued to Calhoon, et al. on May 20, 2008; all of which are incorporated hereinto by reference.

In FIG. **4**C, DC IN **40** is fed into an adjustable rheostat **46** which is controlled by the controller so that the DC OUT **47** falls within a specified range.

FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

This type of conductive line is commonly called poly-wire and consists of multiple interwoven strands of plastic **50**A and **50**B woven into a cord or rope arrangement having intertwined therein exposed metal wires **51**A and **51**B. While this illustration shows two plastic strands and two metal wires, any number of possible combinations is possible.

The exposed metal wires **51**A and **51**B attract the atmospheric static charge and transmit the charge down to the base unit (not shown).

FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

This conductive line utilizes a tube **60** having an outer layer **62** of PET Film (Biaxially-oriented polyethylene terephtalate polyester film) which provides exceptionally high tensile strength and is chemically and dimensionally stable. The tube has an ideal diameter of between two and three inches.

An interior metal coating **61** provides an initial conduit for the flow of static charge. The static charge through the metal forces the tube to expand due to the repulsion experienced by like charges. Further, the flow of electricity causes the interior of the tube **60** to become ionized to provide an additional pathway for the atmospheric static charges to the base unit (not shown).

Because outer layer **62** provides a gas barrier, the resulting ionization is not dissipated by air currents, thereby providing a highly stable pathway.

FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

In this embodiment, controller box **70**, resting on insulating pad **72**, is in communication with the sensors as described above. Using the input from these sensors, when there is flow of electricity through the base unit, warning flashing light **71** is illuminated. To electrically neutralize the mechanism, switch **73** is activated to pass any existing current into the ground **74**.

FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

Referencing FIG. **8**A, enhanced electrical collection lead **82** is a wire mesh which is in electrical communication with conductive line **81** and balloon **80**. Because of the significant amount of metal exposed by enhanced electrical collection lead **82**, more static electricity from the atmosphere is drawn to the collection lead **82**, and then down conductive line **81** to the base unit (not shown).

Conductive lead **82** is positioned proximate to balloon **80**.

In FIG. **8**B, poly-wire **83** has enhanced electrical collection leads **84** wrapped therearound. Collection leads **84** have pointed ends **85**A and **85**B which have a propensity to attract more electricity than rounded ends do.

It is clear from the foregoing that the present invention captures an entirely new source of electrical energy.

What is claimed is:

1. A mechanism to tap an electrical source comprising:
- a) a lighter than air balloon suspended in the atmosphere;
- b) a base unit having a spool of conductive line on a winch motor, one end of said conductive line secured to said lighter than air balloon, a portion of said conductive line collecting electricity in the atmosphere, said winch motor capable of selectively extending or withdrawing said conductive line from said spool;
- c) an insulator electrically isolating said conductive line from ground;
- d) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load being powered by collected electricity from said conductive line;
- e) an electrical flow sensor monitoring electrical flow through said conductor and generating an electrical flow indicia indicative of said electrical flow in said conductor; and,

f) a controller receiving said electrical flow indicia and selectively operating said winch motor such that said electrical flow indicia remains within a selected operating range.

2. The mechanism to tap an electrical source according to claim **1**, wherein said selected operating range is established by an operator.

3. The mechanism to tap an electrical source according to claim **2**, further including a warning light activated when said electrical flow indicia is non-zero.

4. The mechanism to tap an electrical source according to claim **1**,

a) further including a lightning sensor generating a lightning presence indicia indicative of lightning within a prescribed range, said presence indicia being communicated to said controller; and,

b) wherein said control mechanism, in response to said lightning presence indicia, operates said winch motor to withdraw substantially all of said conductive line onto said spool.

5. The mechanism to tap an electrical source according to claim **4**, wherein said prescribed range is established by an operator.

6. The mechanism to tap an electrical source according to claim **1**, further including an electrical collection enhancement lead in electrical contact with a first end of said conductive material, said electrical collection enhancement lead configured to attract static electricity.

7. The mechanism to tap an electrical source according to claim **6**, wherein said electrical collection enhancement lead is positioned proximate to said lighter than air balloon.

8. The mechanism to tap an electrical source according to claim **7**, wherein said electrical collection enhancement lead includes at least two pointed electrical conductors.

9. The mechanism to tap an electrical source according to claim **1**, wherein said insulator electrically isolates said conductive line from said winch motor.

10. The mechanism to tap an electrical source according to claim **1**, wherein said insulator electrically isolates said base unit from ground.

11. A mechanism comprising:

a) an airborne aircraft having a conductive line secured to a winch capable of extending or withdrawing said conductive line from a spool, when said airborne aircraft is aloft, said conductive line collecting electricity from the atmosphere;

b) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load such that collected electricity from said conductive line powers said load;

c) an electrical flow sensor monitoring electrical flow through said conductor and generating an electrical flow indicia indicative of said electrical flow in said conductor; and,

d) a controller receiving said electrical flow indicia adjusting an altitude of said airborne aircraft via said winch such that said electrical flow indicia remains within a selected operating range.

12. The mechanism to tap an electrical source according to claim **11**,

a) further including a lightning sensor communicating with said controller; and,

b) wherein said controller, in response to selected signals from said lightning sensor withdraws substantially all of said conductive line.

13. A mechanism to tap an electrical source comprising:

a) a lighter than air balloon suspended in the atmosphere;

b) a base unit having a spool of conductive line on a winch motor, one end of said conductive line suspended by said balloon, a portion of said conductive line collecting electricity from the atmosphere, said winch motor capable of adjusting an altitude of said lighter than air balloon by selectively extending or withdrawing said conductive line from said spool;

c) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load being powered by said collected electricity from said conductive line;

d) a sensor array having,

1) an electrical flow sensor monitoring electrical flow through said conductor and generating an electrical flow indicia indicative of said electrical flow in said conductor, and,

2) a lightning sensor monitoring existence of proximate lightning; and,

e) a controller responsive to said electrical flow indicia from said sensor array to selectively operate said winch motor.

14. The mechanism to tap an electrical source according to claim **13**,

a) further including a warning light; and,

b) wherein said controller activates said warning light when said electrical flow in said conductor is non-zero.

15. The mechanism to tap an electrical source according to claim **14**, further including an electrical collection enhancement lead in electrical contact with said conductive material, said electrical collection enhancement lead configured to attract static electricity and positioned proximate to said lighter than air balloon.

(57) **ABSTRACT**

Systems, methods and apparatus for harvesting atmospheric electricity are provided. The system includes a laser configured to form a plasma filament and a collector configured to collect electricity flowing along the plasma filament. The plasma filament comprises an electrically conducting plasma filament. Atmospheric electricity may be collected by having the plasma filament form at least a part of a conducting path: (1) between ground and a cloud, (2) between differently charged regions of the same cloud, (3) between differently charged regions of different clouds, and (4) between different regions of atmosphere, where there is a vertical voltage gradient. When the plasma filament is not long enough to form the entire conducting path, a lightning may be triggered to complete the conducting path needed to collect atmospheric electricity.

SYSTEM FOR HARVESTING ATMOSPHERIC ELECTRICITY

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT

[0001] Not applicable.

FIELD OF THE INVENTION

[0002] The subject technology relates in general to a system for harvesting atmospheric electricity, and more particularly to a system that uses a laser to form an electrically conducting plasma filament for harvesting atmospheric electricity.

BACKGROUND

[0003] It is well known that large quantities of electrical energy are present in the atmosphere and in lightning. Lightning was one of the first forms of electricity harnessed in the modern age by Benjamin Franklin in his famous kite experiment.

[0004] A lightning discharge typically contains on the order of le Joules of energy. It has been estimated that the total electrical power of lightning across the Earth is of the order of 10^{12} watts. Collection of electrical energy from clouds associated with lightning is a problem that needs to be resolved.

[0005] Lightning is but a small part of the total electrical activity of the atmosphere. When a local build up of charge above the Earth exceeds the local breakdown potential of the atmosphere a lightning discharge occurs. However, there is a continual invisible flow of charge from Ionosphere to Earth occurring day and night over the entire surface of the globe, which exceeds the global lightning power output by many times. The source of this flow of charge from the atmosphere to Earth is the Sun. Radiation from the Sun helps form most of the ions found in the Ionosphere, a highly charged region above the atmosphere, through ionization of atmospheric molecules. Solar radiation, particularly in the UV and soft x-ray bands, consist of photons whose energies are well suited to ionization. The Sun also emits continuously a solar wind of positively charged particles. These are captured by the Earth's magnetic field and further contribute to the Ionosphere. The positively charged region in the Ionosphere in turn induces (by electrostatic induction) a negative charge on the surface of the Earth. The Earth becomes in effect an enormous spherical capacitor. A potential gradient or electric field is thus established between the two "plates" of this capacitor, the Ionosphere (or Electrosphere) and the surface of the Earth. While the upper strata of the atmosphere conduct electricity reasonably well, the lower levels act as an insulator or dielectric. Near the surface of the Earth, this electrostatic potential gradient is on the order of about 100 Vm^{-1} in summer, rising to 300 Vm^{-1} in winter. This flow of charge can be tapped and directed to provide useable electrical power. This source of atmospheric electricity has the following advantages: (1) Simple and robust technology; (2) Low cost technology—much cheaper than photovoltaics or wind turbines; (3) Available day and night in all weather conditions—in fact, more power is produced at night than during the day; and (4) Available at any point on the Earth's surface. Collection of this source of atmospheric electricity is another problem that needs to be resolved.

SUMMARY

[0006] According to various aspects of the subject technology, a system for harvesting atmospheric electricity is provided that solves some or all of the foregoing problems. In some aspects, the system may be used to harvest atmospheric electricity arising from an electrostatic potential gradient: (1) between ground and a cloud, (2) between differently charged regions of the same cloud, (3) between differently charged regions of different clouds, and (4) between different regions of atmosphere, where there is a vertical voltage gradient. In other aspects, the system may be used to harvest atmospheric electricity arising from an electrostatic potential gradient between the Ionosphere (or Electrosphere) and the surface of the Earth.

[0007] According to various aspects of the subject technology, a system for harvesting atmospheric electricity is provided. The system comprises a laser configured to form a plasma filament. The system also comprises a collector configured to collect electricity flowing along the plasma filament.

[0008] According to various aspects of the subject technology, a method for harvesting atmospheric electricity is provided. The method comprises forming a plasma filament with a laser. The method also comprises collecting electricity flowing along the plasma filament.

[0009] According to various aspects of the subject technology, an apparatus for harvesting atmospheric electricity is provided. The apparatus comprises means for forming a plasma filament with a laser. The system also comprises means for collecting electricity flowing along the plasma filament.

[0010] It is understood that other configurations of the subject technology will become readily apparent to those skilled in the art from the following detailed description, wherein various configurations of the subject technology are shown and described by way of illustration. As will be realized, the subject technology is capable of other and different configurations and its several details are capable of modification in various other respects, all without departing from the scope of the subject technology. Accordingly, the drawings and detailed description are to be regarded as illustrative in nature and not as restrictive.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] The accompanying drawings, which are included to provide further understanding of the subject technology and are incorporated in and constitute a part of this specification, illustrate aspects of the subject technology and together with the description serve to explain the principles of the subject technology.

[0012] FIG. **1** illustrates a first example of a system for harvesting atmospheric electricity. The system comprises a laser configured to form a plasma filament and a collector configured to collect electricity flowing along the plasma filament. The plasma filament forms a conducting path between ground and a cloud.

[0013] FIG. **2** illustrates a second example of a system for harvesting atmospheric electricity. A plasma filament and a lightning together form a conducting path between ground and a cloud. A condensing mirror directs the beam of laser towards the cloud.

[0014] FIG. **3**A illustrates a third example of a system for harvesting atmospheric electricity. A laser system situated on an airplane forms two plasma filaments that together complete a conducting path between a first region of a cloud and a second region of the cloud. The first region of the cloud and the second region of the cloud carry opposite electric charges. A collector configured to collect electricity flowing along the two plasma filaments is also situated on the same airplane as the laser system.

[0015] FIG. **3**B illustrates a fourth example of a system for harvesting atmospheric electricity. It is similar to FIG. **3**A, except two lightnings complete the conducting path between a first region of a cloud and a second region of the cloud (i.e., a first lightning electrically connects the first region of the cloud to one of the plasma filaments and a second lightning electrically connects the second region of the cloud to the other plasma filament).

[0016] FIG. **4** illustrates a fifth example of a system for harvesting atmospheric electricity. A laser system situated on an airplane forms two plasma filaments that together complete a conducting path between a first cloud and a second cloud. The region of the first cloud that is connected to the first plasma filament and the region of the second cloud that is connected to the second plasma filament carry opposite electric charges.

[0017] FIG. **5** illustrates a sixth example of a system for harvesting atmospheric electricity. A laser situated on an airplane forms a plasma filament that completes a conducting path between a first region of atmosphere and a second region of atmosphere. A collector situated on the same airplane as the laser can collect electricity flowing along the plasma filament, because a vertical voltage gradient exists between the first region of atmosphere and the second region of atmosphere.

[0018] FIG. **6** illustrates an example of a collector configured to collect electricity flowing along the plasma filament. The collector may be a charge collection circuit characterized by capacitance, inductance, and resistance. The electricity may be collected by charging a capacitor.

DETAILED DESCRIPTION

[0019] The detailed description set forth below is intended as a description of various configurations of the subject technology and is not intended to represent the only configurations in which the subject technology may be practiced. The appended drawings are incorporated herein and constitute a part of the detailed description. The detailed description includes specific details for the purpose of providing a thorough understanding of the subject technology. However, it will be apparent to those skilled in the art that the subject technology may be practiced without these specific details. In some instances, well-known structures and components are shown in block diagram form in order to avoid obscuring the concepts of the subject technology. Like components are labeled with identical element numbers for ease of understanding.

[0020] FIG. **1** illustrates a first example of a system **100** for harvesting atmospheric electricity. The system **100** comprises a laser **110** configured to form a plasma filament **120** and a collector **130** configured to collect electricity flowing along the plasma filament **120**. The plasma filament **120** forms a conducting path between ground and a cloud **140**.

[0021] The plasma filament **120** comprises an electrically conducting plasma filament. The plasma comprises of electrons and positive ions. The electrically conducting plasma filament may be formed in atmosphere using an ultra short pulse laser (USPL). The USPL forms a plasma filament by raising the conductivity of a very small diameter channel (~100 microns or less) for a very brief time. The propagation of high power (~10^{14} W/cm^2) pulses from the USPL is accompanied by filamentation—self-channeling of femtosecond laser pulses in stable high-intensity light filaments with ~100 microns diameters (so that the Kerr effect focusing balances defocusing due to plasma formation). This filamentation keeps the beam virtually free of diffraction divergence. The long plasma strings have high electron densities (10^{16}/cm^3) which support high conductivities. The ionization of air at these intensities results from multi-photon processes. Filamentation has been produced and detected at altitudes as high as 13-20 km. Almost no beam scattering occurs in filamentation phenomenon, and virtually all the pulse energy is invested in ionization of air molecules. With the typical electron density and channel diameter, a 160 mJ pulse is sufficient to generate a 1 km long channel.

[0022] Once initiated, plasma filaments cannot go on forever, and typically only propagate a kilometer or so before energy depletion and exhaustion. However, by using two coaxial USPL projection optics having different time-lensing parameters, a near and far filament could be initiated in a "daisy-chain" to extend the total length of the conductive channel. The onset of filamentation in the far filament is time-lensed to coincide with the exhaustion range of the near filament. Additionally, using negative chirp, femtosecond laser pulses can propagate almost without loss until different frequency components of the wave packet, propagating at different speeds due to dispersion in air, come together at a certain desired location so that the laser intensity there exceeds the filamentation threshold, resulting in long ionized filaments created at a distance of up to several miles from the laser source. In other words, negative chirp is used to essentially focus a beam of the laser at a desired distance to form the plasma filament there. Accordingly, this technique may be used to move the starting point and to extend the length of the plasma filament.

[0023] The size, electrical conductivity, and lifetime of the plasma filaments are enhanced by an auxiliary radio-frequency electromagnetic waves or microwaves. The plasma filament may act like an antenna to absorb the auxiliary radio-frequency (RF) electromagnetic waves or microwaves.

[0024] The pulsed collection of electric charge and energy is repeated with an optimal (possibly very high) repetition rate of the pulsed laser and of the auxiliary RF waves or microwaves. The energy collected per one pulse should exceed the energy spent on creating and enhancing the plasma filaments, so that the net energy collected is positive. The optimal pulse repetition rate (PRR) depends upon atmospheric conditions which can vary widely over even short time durations. As a general rule, one tries to tune the repetition rate to the plasma relaxation time (the ion-electron recombination time) so that the conductivity of the filament remain as high as is optimal given the atmospheric conditions at the time. A feedback control system that varies the PRR as well as the rest of the pulse-shaping parameters may be employed to optimize the net power production of the system. For more information regarding pulse shaping and tailoring, which is the central theme of the field called "quantum control", please see A. Assion, T. Baumert, M. Bergt, T. Brixner, B. Kiefer, V. Seyfried, M. Strehle, G. Gerber (30 October). "Control of Chemical Reactions by Feedback-Optimized

Phase-Shaped Femtosecond Laser Pulses". Science 282 (5390): 919-922. doi:10.1126/science.282.5390.919. PMID 9794756.

[0025] FIG. **2** illustrates a second example of a system **200** for harvesting atmospheric electricity. A plasma filament **120** and a lightning **210** together form a conducting path between ground and a cloud **140**. A condensing mirror **220** directs the beam of laser **110** towards the cloud **140**. A collector **130** is configured to collect electricity flowing along the plasma filament **120**.

[0026] In the case of electricity collection from the cloud **140**, the initial and RF-enhanced plasma filaments can be relatively short, not reaching all the way from ground to the cloud **140**. The relatively short plasma filament can be optimized so that it would trigger propagation of the so-called leader (as in natural lightning), which would effectively use the energy and potential of the cloud to eventually create an electrically conducting path between ground and the cloud **140**. The final conducting path would comprise of a plasma filament **120** and a lightning **210**.

[0027] It is not shown in the figures, but alternatively both the laser **110** and the collector **130** may be placed on a mobile device, which moves together with the cloud. One such mobile device may be a vehicle moving on the ground, but another such mobile device may be an airplane flying in the air. In the case of an airplane flying in the air, plasma filaments may be formed by the laser to reach both ground and the cloud at the same time. In the event the plasma filament directed at ground is not long enough to reach ground, a lightning may also be formed to complete the conducting path to ground.

[0028] FIG. 3A illustrates a third example of a system **300** for harvesting atmospheric electricity. A laser system situated on an airplane **310** forms two plasma filaments (**321**, **322**) that together complete a conducting path between a first region **331** of a cloud **330** and a second region **332** of the cloud **330**. The first region **331** of the cloud **330** and the second region **332** of the cloud **330** carry opposite electric charges. In the example shown here, the first region **331** of the cloud **330** carries positive electric charges, while the second region **332** of the cloud **330** carries negative electric charges. A collector configured to collect electricity flowing along the two plasma filaments is also situated on the same airplane **310** as the laser. Positive and negative charges are naturally separated within the cloud, so this example makes use of the electrostatic potential gradient between different regions of the same cloud.

[0029] FIG. 3B illustrates a fourth example of the system **300** for harvesting atmospheric electricity. It is similar to FIG. 3A, except two lightnings (**341**, **342**) complete the conducting path between a first region **331** of a cloud **330** and a second region **332** of the cloud **330** (i.e., a first lightning **341** electrically connects the first region **331** of the cloud **330** to one of the plasma filaments **321** and a second lightning **342** electrically connects the second region **332** of the cloud **330** to the other plasma filaments **322**). The lightning formation is again because the initial and RF-enhanced plasma filaments can be relatively short, not reaching all the way from the collector situated on airplane **310** to the cloud **330**. These relatively short plasma filaments can be optimized so that they would trigger propagation of the so-called leader (as in natural lightning), which would eventually create an electrically conducting path between the two regions of cloud **330** via a connection through airplane **310**. The final conducting path would comprise of two plasma filaments (**321**, **322**) and two lightnings (**341**, **342**). Of course, one of the lightnings may not be formed, if one of the plasma filament can reach all the way from airplane **310** to cloud **330**.

[0030] FIG. **4** illustrates a fifth example of the system **300** for harvesting atmospheric electricity. A laser system situated on an airplane **310** forms two plasma filaments (**421**, **431**) that together complete a conducting path between a first cloud **420** and a second cloud **430**. The region **422** of the first cloud **420** that is connected to the first plasma filament **421** and the region **432** of the second cloud **430** that is connected to the second plasma filament **431** carry opposite electric charges. In the example shown here, region **422** of cloud **420** carries positive electric charges, while region **432** of cloud **430** carry negative electric charges. Positive and negative charges are naturally separated within the cloud, so this example makes use of the electrostatic potential gradient between different regions of different clouds. Once again, in case one of the plasma filament cannot reach all the way from airplane **310** to any one of the clouds, then lightning may be formed to complete an electrically conducting path from airplane **310** to any one of the clouds. But these embodiments are not shown in the figures.

[0031] FIG. **5** illustrates a sixth example of the system **300** for harvesting atmospheric electricity. A laser system situated on an airplane **310** forms a plasma filament **501** that completes a conducting path between a first region **510** of atmosphere and a second region **520** of atmosphere. A collector situated on the same airplane **310** as the laser system can collect electricity flowing along the plasma filament **501**, because a vertical voltage gradient exists between the first region **510** of atmosphere and the second region **520** of atmosphere. Because no clouds are needed for this embodiment, atmospheric electricity collection is possible under fair weather conditions (relying on the naturally existing vertical voltage gradient in the atmosphere) as well as under foul weather conditions.

[0032] FIG. **6** illustrates an example of a collector **130** configured to collect electricity flowing along a plasma filament **620**. The collector may be a charge collection circuit characterized by capacitance **631**, inductance **632**, and resistance **633**. The electricity may be collected by charging a capacitor associated with capacitance **631**. Battery **610** represents these naturally existing voltage sources: (1) between ground and a cloud, (2) between differently charged regions of the same cloud, (3) between differently charged regions of different clouds, and (4) between different regions of atmosphere, where there is a vertical voltage gradient. The plasma filament **620** can, for the purpose of analysis and optimization of the charge collection process, be viewed as electromagnetic transmission lines characterized by their effective capacitance, inductance, and resistance per unit length. Accordingly, the parameters of the charge collection circuit and of the effective transmission line representing the plasma filaments are optimized, so as to maximize the net charge and energy collected (minus the energy spent on generating and enhancing the plasma filaments).

[0033] The foregoing description is provided to enable a person skilled in the art to practice the various configurations described herein. While the subject technology has been particularly described with reference to the various figures and configurations, it should be understood that these are for illustration purposes only and should not be taken as limiting the scope of the subject technology.

[0034] There may be many other ways to implement the subject technology. Various functions and elements described herein may be partitioned differently from those shown without departing from the scope of the subject technology. Various modifications to these configurations will be readily apparent to those skilled in the art, and generic principles defined herein may be applied to other configurations. Thus, many changes and modifications may be made to the subject technology, by one having ordinary skill in the art, without departing from the scope of the subject technology.

[0035] It is understood that the specific order or hierarchy of steps in the processes disclosed is an illustration of exemplary approaches. Based upon design preferences, it is understood that the specific order or hierarchy of steps in the processes may be rearranged. Some of the steps may be performed simultaneously. The accompanying method claims present elements of the various steps in a sample order, and are not meant to be limited to the specific order or hierarchy presented.

[0036] A phrase such as "an aspect" does not imply that such aspect is essential to the subject technology or that such aspect applies to all configurations of the subject technology. A disclosure relating to an aspect may apply to all configurations, or one or more configurations. An aspect may provide one or more examples of the disclosure. A phrase such as an "aspect" may refer to one or more aspects and vice versa. A phrase such as an "embodiment" does not imply that such embodiment is essential to the subject technology or that such embodiment applies to all configurations of the subject technology. A disclosure relating to an embodiment may apply to all embodiments, or one or more embodiments. An embodiment may provide one or more examples of the disclosure. A phrase such an "embodiment" may refer to one or more embodiments and vice versa. A phrase such as a "configuration" does not imply that such configuration is essential to the subject technology or that such configuration applies to all configurations of the subject technology. A disclosure relating to a configuration may apply to all configurations, or one or more configurations. A configuration may provide one or more examples of the disclosure. A phrase such as a "configuration" may refer to one or more configurations and vice versa.

[0037] Furthermore, to the extent that the term "include," "have," or the like is used in the description or the claims, such term is intended to be inclusive in a manner similar to the term "comprise" as "comprise" is interpreted when employed as a transitional word in a claim.

[0038] The word "exemplary" is used herein to mean "serving as an example, instance, or illustration." Any embodiment described herein as "exemplary" is not necessarily to be construed as preferred or advantageous over other embodiments.

[0039] A reference to an element in the singular is not intended to mean "one and only one" unless specifically stated, but rather "one or more." The term "some" refers to one or more. Underlined and/or italicized headings and subheadings are used for convenience only, do not limit the subject technology, and are not referred to in connection with the interpretation of the description of the subject technology. All structural and functional equivalents to the elements of the various configurations described throughout this disclosure that are known or later come to be known to those of ordinary skill in the art are expressly incorporated herein by reference and intended to be encompassed by the subject technology. Moreover, nothing disclosed herein is intended to be dedicated to the public regardless of whether such disclosure is explicitly recited in the above description.

What is claimed is the following:

1. A system for harvesting atmospheric electricity, comprising:

a laser configured to form a plasma filament; and

a collector configured to collect electricity flowing along the plasma filament.

2. The system of claim **1**, wherein the plasma filament comprises an electrically conducting plasma filament.

3. The system of claim **1**, wherein the laser is a pulsed laser.

4. The system of claim **3**, wherein the pulsed laser is pulsed at an optimal repetition rate.

5. The system of claim **1**, wherein the plasma filament is enhanced by a plurality of auxiliary electromagnetic waves.

6. The system of claim **5**, wherein the plurality of auxiliary electromagnetic waves comprises at least one of radio-frequency waves or microwaves.

7. The system of claim **1**, wherein the plasma filament forms at least a part of a conducting path between ground and a cloud.

8. The system of claim **7**, wherein at least one lightning forms another part of the conducting path between ground and the cloud.

9. The system of claim **1**, wherein the plasma filament forms at least a part of a conducting path between a first region of a cloud and a second region of the cloud.

10. The system of claim **9**, wherein at least one lightning forms another part of the conducting path between the first region of the cloud and the second region of the cloud.

11. The system of claim **1**, wherein the plasma filament forms at least a part of a conducting path between a first cloud and a second cloud.

12. The system of claim **1**, wherein the plasma filament completes a conducting path between a first region of atmosphere and a second region of atmosphere.

13. The system of claim **12**, wherein a vertical voltage gradient exists between the first region of atmosphere and the second region of atmosphere.

14. The system of claim **1**, wherein the collector comprises a charge collection circuit.

15. The system of claim **1**, wherein the laser is situated on ground.

16. The system of claim **1**, wherein the laser is situated on a mobile device.

17. The system of claim **16**, wherein the mobile device is an airplane.

18. The system of claim **1**, wherein negative chirp is used to move the starting point of formation of the plasma filament to a desired location.

19. A method for harvesting atmospheric electricity, the method comprising:

forming a plasma filament with a laser; and

collecting electricity flowing along the plasma filament.

20. An apparatus for harvesting atmospheric electricity, the apparatus comprising:

means for forming a plasma filament with a laser; and

means for collecting electricity flowing along the plasma filament.

* * * * *

Capacitors we used are electrolytic rated at 400 volts x 47 uF put in series to equal 6,000 volts, the diodes we used were silicon 1000 volt 2 amp placed in series to equal 6,000 volts......... Ground was connected to laboratory wall out let ground.

If you decide to try Tesla's experiment by pumping DC into the ground be careful, I tried this and it does work but is very dangerous to you or your neighbors. If someone is taking a shower or using water they can get killed or shocked. do this experiment far away from humans and animals. you can get far more energy out than you put in. I will not tell you much more because it is such a dangerous experiment.

POWERING ELECTRICAL DEVICES WITH ENERGY ABSTRACTED FROM THE ATMOSPHERE

Lloyd R. Crump, Silver Spring, Md.

Application March 12, 1954, Serial No. 415,986
1 Claim. (Cl. 321—2)
(Granted under Title 35, U. S. Code (1952), sec. 266)

The invention described herein may be manufactured and used by or for the Government for governmental purposes without payment to me of any royalty thereon.

This invention relates to the convenient and economical provision of power for the operation of electronic circuits and devices using transistors, and of other electrical devices having modest power requirements.

A great advantage of transistors, and a major reason for their enthusiastic reception since their introduction a few years ago, is the fact that they will operate satisfactorily with very low supply voltages and currents. One milliwatt or even less is sufficient to power a transistor in many applications. Various batteries have been developed to provide, in a minimum of space, the relatively minute amounts of power needed by transistors.

My invention provides methods and means that permit transistor circuits, and also other low-powered electrical devices, to be economically and conveniently operated without any batteries whatever, and indeed without any power supply whatever as power supplies are ordinarily conceived.

The invention centers around my discovery that it is practicable to construct operative transistor circuits that are able to abstract from the atmosphere sufficient electromagnetic energy to provide all necessary supply voltages and currents for their own operation. Circuits and devices powered according to my invention will operate indefinitely without any local power source whatever.

I have successfully constructed and demonstrated such circuits. For example, I have constructed a batteryless transistor radio receiver on which I have listened to either nearby or distant broadcast stations as desired, using either headphones or a loudspeaker; this receiver has been powered entirely by electromagnetic energy abstracted from the atmosphere.

From the successful operation of this receiver, and from other experimental work, it becomes clear that, by the methods and means of the invention, a great variety of practical and useful transistor circuits can be powered entirely by energy abstracted from the atmosphere.

Furthermore, as will become apparent below, my invention is applicable to the powering of other electrical devices requiring relatively small amounts of power.

An object of the present invention is to provide methods and means for powering transistor circuits entirely from radiofrequency energy abstracted from the atmosphere.

Another object is to provide methods and means for powering remote radio receivers, low-powered radio transmitters, and other low-powered electrical devices, with energy received by radio from a master station, so that no local power supplies are needed by the devices and so that the powering or non-powering of the remote device is under the control of the master station.

A further object is to provide methods and means for powering transistor circuits and other low-powered electrical devices with radiofrequency energy received from one or more remote radio transmitters.

Other objects, aspects, uses, and advantages of the invention will become apparent from the following description and from the drawing.

Figure 1 is a schematic diagram of a transistor radio receiver in which all necessary power is supplied by energy abstracted from the atmosphere in accordance with the invention.

Figure 2 is a schematic diagram showing a general application of the invention to provide direct-current power to a load.

Figure 3 is a schematic diagram of a system for obtaining a high energy D.-C. source at a high voltage level using energy abstracted from the atmosphere.

Referring to Figure 1, a receiving antenna **1** is connected to antenna coupling coils **2** and **3**, the other ends of which are connected to ground. A parallel resonant circuit consisting of coil **5** and capacitor **6** is coupled to coil **2**. A second parallel resonant circuit consisting of coil **7** and capacitor **10** is coupled to coil **3**. A third parallel resonant circuit consisting of coil **11** and capacitor **12** is also coupled to coil **3**.

Coil **5** and capacitor **6** are tuned to the frequency of a radio transmitter from which it is desired to receive information—for instance, an amplitude-modulated standard broadcast station. The signal received from this transmitter need not be strong. The signal is detected by diode **15** to obtain an audio-frequency information signal. This audio signal is coupled through a capacitor **16** and is amplified by a circuit that includes a transistor **17** having a base **20**, an emitter **21**, and a collector **22**. The amplified audio output of the transistor is coupled through an audio transformer **23** to an electroacoustical transducer, preferably a permanent-magnet dynamic loudspeaker **25** as shown.

The novelty of the invention lies largely in the method and means by which the necessary direct-current power is supplied to the emitter and collector circuits of transistor **17**. This method and means will now be described.

Coil **7** and capacitor **10**, and also coil **11** and capacitor **12**, are tuned to receive radio signals of relatively high strength. It does not matter whether these signals contain information. These power signals are rectified by diodes **26** and **27** to provide direct-current power that is filtered by capacitors **30** and **31**. The D.-C. power thus obtained is utilized to power the transistor **17**.

In the circuit shown, two tuned circuits (coil **7** and capacitor **10**, and coil **11** and capacitor **12**) are tuned to power signals and the D.-C. voltages obtained from each are connected in series. The tuned power circuits may be tuned to the same or different power signals. Under certain circumstances it may be desirable to use more than two tuned power circuits and to tune them to more than two power signals; in this way power can be obtained from several signals and combined. On the other hand, if a strong power signal is available, a single tuned power circuit may suffice to give the needed D.-C. power.

Even weak information signals can be received successfully. A plurality of transistor amplifier stages can be used if desired, or other circuits such as superheterodyne circuits can be used. It is merely necessary that a sufficiently strong power signal or signals be available to provide the small amount of D.-C. needed to power the transistors.

If the information signal happens to be strong, it can be used as the power signal; all of the tuned circuits (coil **5** and capacitor **6**, coil **7** and capacitor **10**, coil **11** and capacitor **12**) are tuned to the information signal.

Engineers who have observed my invention in operation have been surprised at the unexpectedly good results obtained, even with readily available power signals of quite moderate strength. For instance, sufficient power for satisfactory operation of a loudspeaker at low volumes is

readily obtained from a 5-kilowatt standard broadcast station 5 miles away, using only an indoor antenna to pick up the power signal as well as information signals. In typical operation under these conditions a D.-C. voltage of about 2.5 to 3 volts is obtained between the emitter and the collector, at a current of about 250 microamperes; D.-C. power input to the transistor is thus of the order of 0.5 to 1 milliwatt. So far as I am aware, no one has ever before discovered and demonstrated the practicability of this method of powering a radio receiver.

Because existing broadcast stations within a radius of a number of miles provide adequate power signals, the invention is readily practicable with existing power signals in almost any location in or near any city in the United States.

Although I have described a transistor radio receiver powered by my invention, it will be readily apparent that the invention is applicable to the powering of any transistor circuit using one or a number of transistors, and to the powering of other devices requiring relatively small amounts of power. For instance, sensitive electromechanical, electrochemical, or electrothermal devices can be operated by the method of the invention.

Referring to Figure 2, which shows a more general embodiment of my invention, an antenna **35** picks up radiofrequency energy from the atmosphere. This energy flows through coil **36**, which is coupled to a tuned circuit consisting of coil **37** and capacitor **40**. The radiofrequency voltage across capacitor **40** is rectified by diode **41** and filtered by a low-pass filter **46** consisting of capacitors **42** and **44** and choke coil **43**. The resulting D.-C. voltage is applied to a load **45**.

In the practice of my invention, larger amounts of power can be obtained for short periods of time by storing received energy in a suitable energy storage device. Stored energy may then be withdrawn at intervals at a more rapid rate than that at which it was received and put into the storage device. In this way the invention can be used to provide short pulses of relatively very high electrical energy. This result can be readily obtained by charging a relatively large capacitor with direct current and then discharging the capacitor rapidly into a load when desired. This rapid discharge can be initiated automatically when the voltage across the capacitor reaches a certain level, or it can be initiated when a transistor radio receiver receives a certain information signal.

Higher voltages can be obtained with the invention by means of well known devices for raising D.-C. voltages as shown in Figure 3. The D.-C. voltage output from the capacitor **44** can be used to power a low frequency transistor oscillator **52** whose A.-C. output is raised to a higher voltage level by the transformer **55**. This relatively high A.-C. voltage can then be rectified by a diode **61** and fed to a capacitor **64** to provide a high energy D.-C. source at a relatively high voltage level at the terminals **69** and **70**. If desired, energy can now be withdrawn from the capacitor **64** at intervals in short pulses of high energy at a high voltage level. Pulsed radio transmission is one of the possible uses for this form of the invention. Other uses would be to provide a single relatively powerful pulse needed to actuate an electrothermal or electromechanical device.

As has been indicated above, in many locations and particularly anywhere in or near most American cities, power signals normally present in the atmosphere are readily available for the easy and convenient practice of the invention. However, the invention also has important applications in systems in which the necessary power signal is generated and transmitted specifically for the operation of the particular system. Such systems can, for example, comprise a master station transmitting all the power that is needed for hundreds or thousands of fixed or mobile transistor receivers or other remote devices over a range of many miles. This eliminates the need for hundreds or thousands, as the case may be, of local power supplies. At the same time, such a system has the advantage that all of the remote devices can be simultaneously activated or deactivated at the will of the master station, simply by starting or stopping the transmission of the power signal. In such systems it will often be advantageous to use power signals of frequencies sufficiently high to permit the use of resonant receiving antennas of small physical dimensions for signal pickup at the remote devices. In addition to the power signal, the master station may transmit an information signal on the same or a different carrier.

Certain types of devices powered entirely by received radio waves are of course well known. The well-known "crystal set" of the early days of radio, which used a diode rectifier to demodulate an amplitude-modulated radiofrequency signal, is an outstanding example of such a device. My invention is readily distinguishable from such prior devices, however. In typical prior devices a modulated radiofrequency signal is applied to a diode to obtain unidirectional half-wave pulses whose amplitudes vary with modulation. These pulses are integrated by means of a capacitor to obtain a unidirectional signal the amplitude of which follows the audiofrequency modulation envelope. If the radiofrequency signal is received with sufficient strength the audio signal may have sufficient power to operate headphones or similar utilization device without power amplification; but the signal is utilized for its information content, rather than to supply non-information-containing power.

My invention, on the other hand, entails the utilization of received radiofrequency energy to supply power to at least one pair of circuit points (across capacitor **31** in Fig. 1, for example), such circuit points requiring power solely for its power content and not for any information or modulation it may contain. In other words, my invention entails the utilization of radiofrequency energy to supply power that would otherwise have to be supplied by batteries, generator, or other local power source.

It will be apparent that the embodiments shown are only exemplary and that various modifications can be made in construction and arrangement within the scope of the invention as defined in the appended claim.

I claim:

An electrical device for obtaining a high energy D.-C. source at a high voltage level using energy abstracted from the atmosphere, said device comprising in combination: resonant means for receiving radio waves, first rectifier means for converting said radio waves into first direct current energy, first capacitor means for storing said first direct current energy, an oscillator powered by said direct current energy, said oscillator producing an A.-C. output, transformer means for raising said A.-C. output to an increased voltage level, second rectifier means for converting the A.-C. output of increased voltage level from said transformer into second direct current energy, and second capacitor means for storing said second direct current energy.

Nikola Tesla

Free Energy *From The* EARTH

Scale up the enclosed methods and you could have

Unlimited Amperage!

By Unlimited we mean you can keep adding more earth cells to your earth power station as you can afford it year by year adding more and more amp power.

Aluminum

Copper

There are many ways to pick up on the free energy in the earth, Just a few are described in these plans. These devices if made right will pick up earth energy that many call ether or static currents as well as acting as high efficient earth battery's. Ether travels through plastic wood etc... Study and research these plans closely there is more to these plans than what you may think. You can learn to get enough power to run your home!

Learning The basic’s of our invention

Experiment #1 How to assemble a 12 vdc system

1. You will have 12- 4" 3/4" copper piping, or If you did not purchase the kit then cut your copper to this size. KIT: take each piece of copper and tape the tops with 1" masking tape.

2. Now using RED LACQUER spray paint (Which you can buy at any hardware store), Paint the outside of the copper all around. (DO NOT PAINT THE INSIDE.) let air dry for 24 hrs. Now remove 1" masking tape.

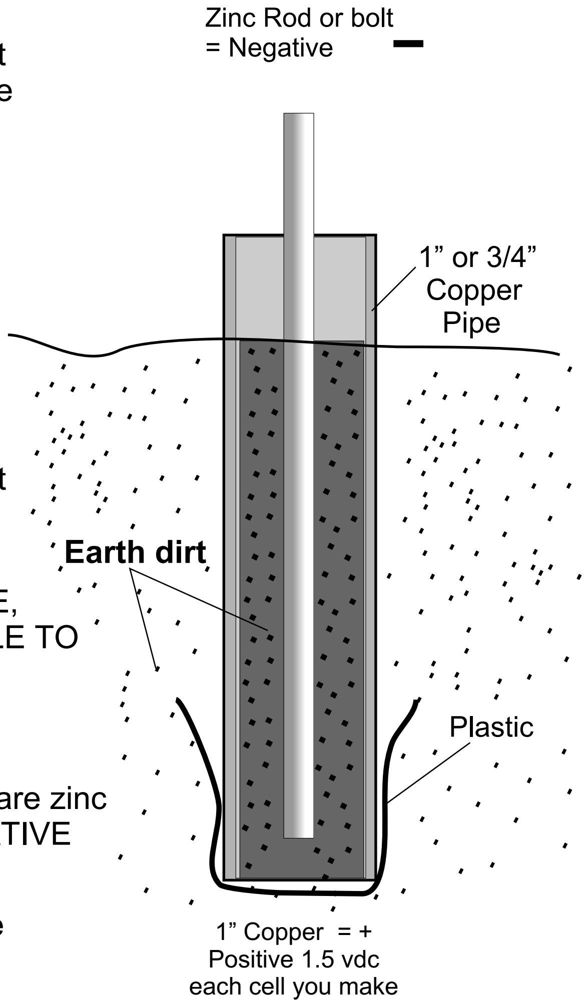
3. Take the copper pipe outside to the area that you are going to use. use a hammer and hammer each one Into the ground up to the 1" copper exposed top. do not let the exposed copper touch the earth in the final placement. Dirt should be moist. Not real dry.

4. Now remove each pipe and place a thick piece of plastic on bottom of copper pipe to cap it. LET IT BE LOSE, DO NOT TAPE IT. YOU WANT RAIN WATER TO BE ABLE TO ESCAPE FROM EACH PIPE, Do not let exposed outside copper touch the earth.

5. Now hammer each pipe back Into the same holes. place each 2" piece of zinc rod (or a long bolt, most bolts are zinc plated) into the center of each pipe. The zinc Is the NEGATIVE and the copper is the + POSITIVE.

6. Now connect them in series to get 12 volts, use clip wire or solder them. If you are going to leave It outside for a long time then make sure connections are soldered and then painted to protect them from the weather. The rain will replenish your earth batteries. Top get more amaperage with this type simply add more copper and zinc rod cells USE 3' PIECES OF COPPER PIPE INSTEAD OF 4" PIPE. THEN CONNECT EVERY ROW OF 12 PIPES IN PARALLEL.. ADD AS MANY ROWS AS YOU NEED UNTIL YOU GET THE DESIRED AMPERAGE YOU WANT. **(THINK BIG!)** This can be a very powerful free energy system for your home or other. Not only will you get an earth battery effect, but you will also be collecting earth currents from ether /static and under ground radio waves as well.

7. The deeper you go with the copper pipe, the more amperage and voltage you can get.



This represents one cell. A qty of 12 to 14 will give you 12 - 14 volts dc when connected in series.

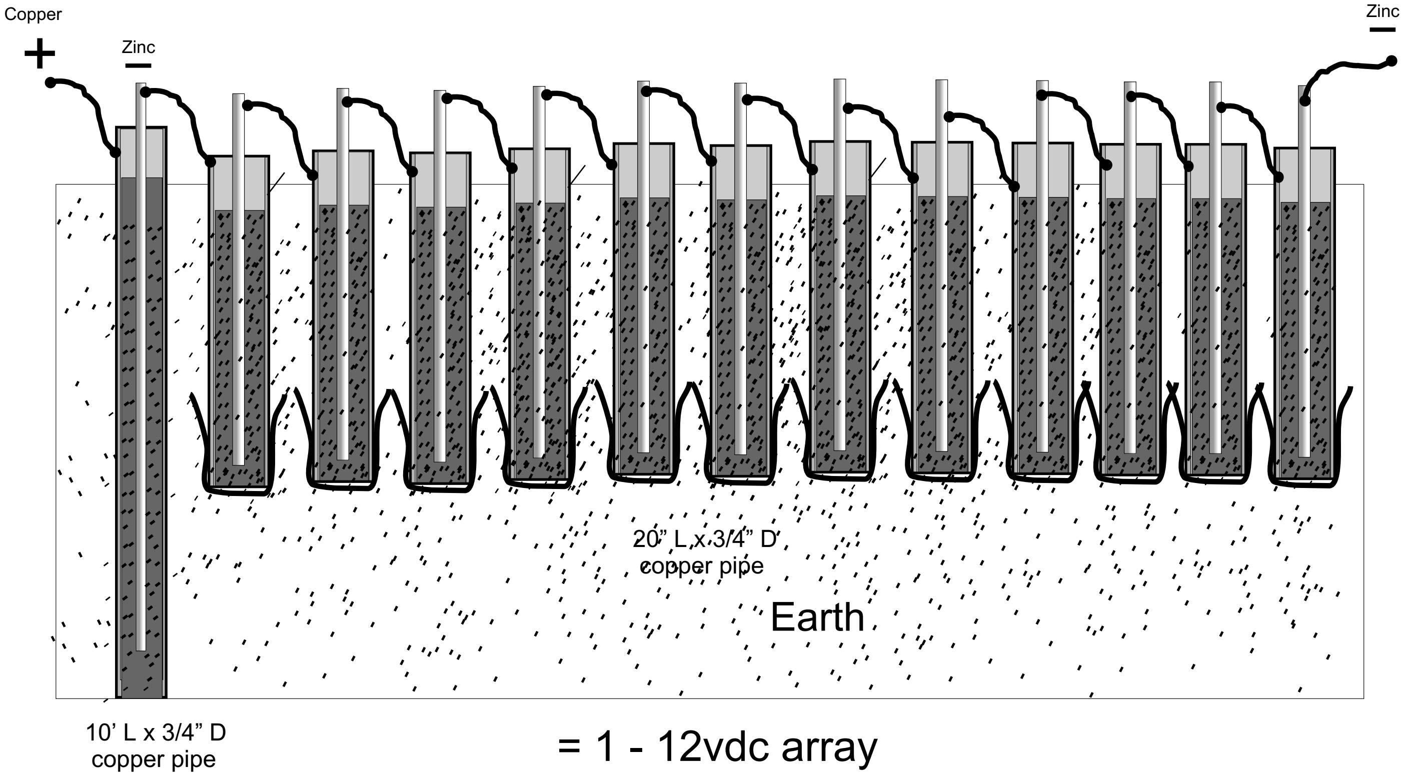
Cut 12 - 4” L x 3/4” copper pipe

Copyright 2002 - 2004 Creative Science & Research

Learning The basic's of our invention

Experiment #2 How to assemble a 12 vdc system

This is just an example to go by and is not the best way but is low in efficiency! See our capacitor earth cells, coil type or flat sheet type. They produce far more amperage and voltages than this type.



= 1 - 12vdc array

NOTICE: Do not paint the 10 foot copper cell. Keep all copper exposed to the earth. The more exposed copper the better. For higher amperage output, use a zinc or aluminum rod 10/16" Diameter which will leave a space of more than 1/16" to the copper.

Advantages of earth powered batteries

1. Free Energy
2. Long Life
3. The collection of aether energy.
4. Cells are also replenished by outside weather. Rain as well as lightning charges.

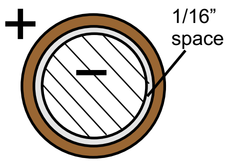
Copyright 2002 - 2004 Creative Science & Research

Learning The basic's of our invention

You can purchase Zinc rods or zinc plated bolts at any hardware store, most all nuts and bolts they sell are zinc coated and will work just fine. They also carry aluminum sheeting. Most hardware stores can order you copper sheeting as well.

Experiment #3 How to assemble a 12 vdc system

This is a simple way to produce more amperage but is not practical, we are only showing you this to educate you. The closer the zinc rod is to the copper the more amperage you will get as well as going deeper into the earth. If you do decide to build this basic set up. It is suggested that you solder all leads very well and dig deep enough into the earth to hide the tops of each cell. By covering the tops with dirt the cells can short out so what you want to do is to paint the exposed tops with lacquer or enamel paint then cover with plastic, cover with dirt and allow both the negative and the positive leads to stick out of the ground. But like I said this is not practical, what your goal should be is to make a very strong uf earth capacitor / battery, This will allow you to pick up and collect earth radiant waves of energy as well as lighting energy during storms, the energy you can collect in a strong lighting storm will amaze you! You must use an antenna on the zinc rod or copper rod. **WARNING! Be careful when collecting lighting it can kill you, be sure the positive and negative wires are not coming into your home. During a storm it is advised to have the lead wires going into a large uf cap bank via a one way diode on the positive lead to the positive of the cap or battery. The earth battery's can be dangerous at times and must be completely buried in the earth so a child, adult or animal can not touch or get to. Our earth capacitor batteries can store and hold thousands of volts. So be careful. Use rubber gloves and clothing to protect yourself. We are not responsible for anything in these plans you build at your own risk.**

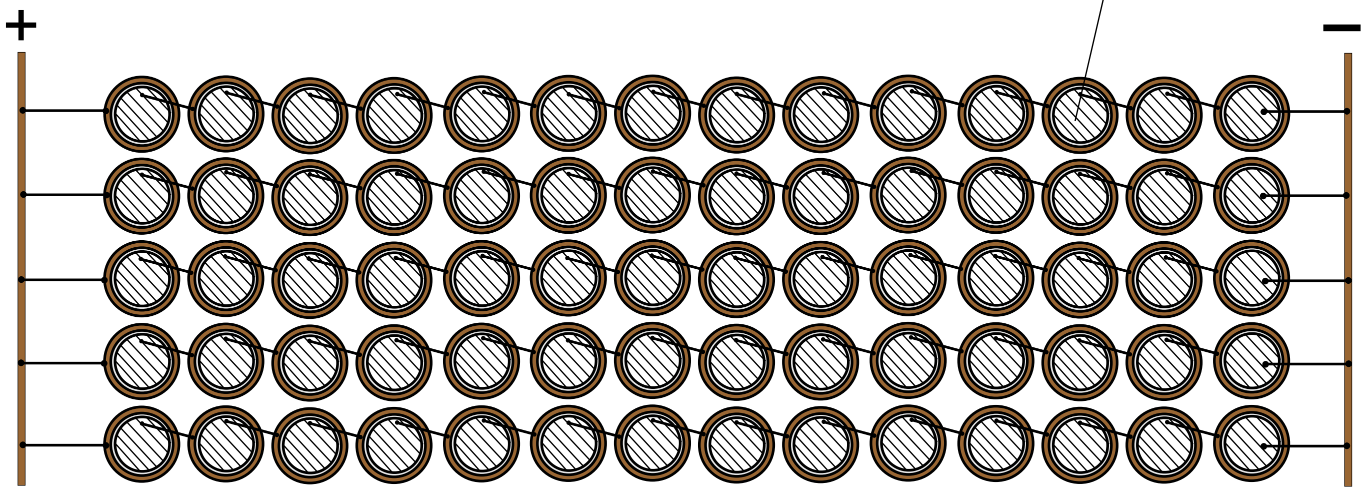


Example of a perfect Zinc rod copper pipe cell

Top view of a 12 volt dc array high amp system

Connect the series arrays in parallel to each other as shown. Or for a high voltage system connect all in series! Pulse the dc into a 10x step up transformer, 15,000 v Neon transf.

Zinc rod can be replaced by using rolled up aluminum sheeting or Zinc sheeting, Use 100% cotton cloth wrapped around the rolled sheeting or rod to give a small space in between the aluminum sheet and copper.

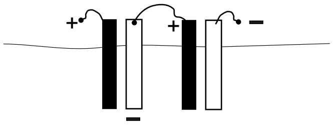


Copyright 2002 - 2004 Creative Science & Research

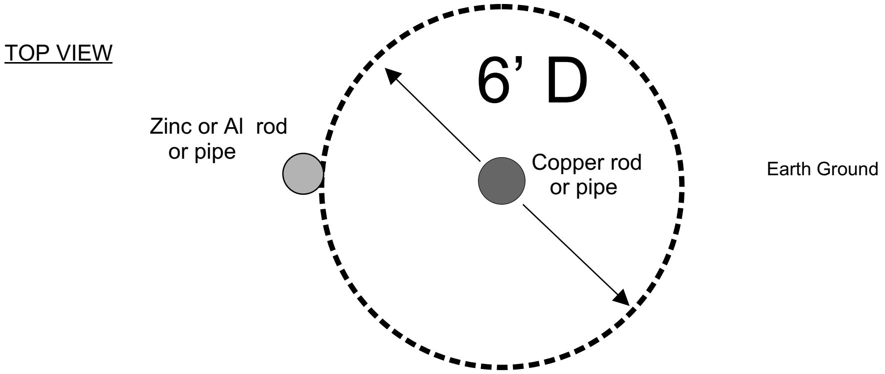
Learning The basic’s of our invention

Experiment #4 The 6 foot spacing method (old way)

There are many US Patents that were Issued back in the 1800's, one of them was issued to a Mr. Deckman. Deckman found that if you take several small pieces of Zinc and Carbon rod and stick them into the ground next to each other and connect them in series (much like a battery) you get very liittle gain at all.



But if you put them 6 feet apart you will get a gain In voltage and they will not cancel one another out. so by doing this you can put them In series to increase your voltage and your volt amps. The theory is that there Is some sort of natural energy VORTEX that takes up about that much space for each unit or cell.



By using this method it will take a lot of ground space, ground space that many people just do not have with the exception of farmers. If you do have the space then think BIG! dig deep and have as many cells as you can get up to 2 to 4 acres. There are much better ways - vs - the old method as you will see. but by using Deckmans old way or our new methods, you can get as much free energy as you want with voltages or amperages as high as you want or desire. The higher the desired amperage the more costly it can get. We are always working to better our inventions to keep the cost down.

Copyright 2002 - 2004 Creative Science & Research

Learning The basic’s of our invention

By using our new system you can get as much voltage or amperage as you want. Just size It to meet your needs or your budget.

How to get AC current for house hold use.

You can convert the incoming dc current to ac by using a home made inverter (which we sell the plans to, **5 kw inverter plans $40 order #579**) or you can purchase a 12 v to 115 vac inverter from a store or solar panel supply house.. If you are planing to make a 115 VAC system this Is the only way you can do it. You can not get AC current from the ground. You must use our system to charge a deep cycle 12 v marine battery, and then connect our 5,000 watt 120 vdc to ac inverter to the battery to run your home. (we do not sell kits or inverters assembled, we only sell the plans at this time.)

More on the basic pipe method

Please note: the dirt level inside each pipe should be up to 1/4" from the top. each pipe should be tightly fliied with dirt. Which will automatically happen when you hammer the pipe into the ground the first time.

Each copper pipe (or cell) should be spaced 1 Inch to 1 1/2 inch apart. Doing this will give you more amperage and voltage.

How to dig a simple deep hole for 8' pipe: There are many ways in which you can do this. you can rent a ground drill bit and rig it up with a electric 2 hp motor or you can use 1" copper pipe.

First: prepare the ground with water to make it moist but not muddy, 2nd: hammer a 1" x 5' copper pipe into the moist ground about 5 inches deep/ then remove it from the ground and take a stick or a water hose to remove the dirt from inside the pipe. Then just repeat the process over and over until you get the desired depth that you want. you can get about 10 feet or more using this method.

WARNINGI BE CAREFUL OF ELECTIC POWER LINES WHEN YOU PLACE OR PULL THE COPPER PIPE FROM THE GROUND, IT WILL KILL YOU IF YOU TOUCH A POWER LINE WITH THE END OF THE COPPER PIPE.

We are dealing with a new type of energy as well as conventional energy < Ether energy can go through rubber/ plastic. Iron, etc....

Copyright 2002 - 2004 Creative Science & Research

What is ether or Radiant energy?

The understanding comes from a very deep study of etheric or static forces, this energy that we are getting out of the ground is what some call LIGHT ETHER, when you separate the light ether from the warm ether you can get these superconductive events. It appears like electricity but it has no heat events related to It.

The point is that the best polarity's of things to get a differential in the light ether is to have a silvered coloured metal and then something that is totally absorbitive/ Like black Carbon.

So now you have something that's the perfect reflector and something that is the perfect absorber, and once you understand what your pulling out of the ground (and that it Is not classic electricity as we get out of a normal type of chemical battery), then your going to be farther down the road to understanding how to get much more power out of this stuff.....

There are researchers now that are getting 1 /2 volt to 2 volts dc on a "Quote" volt meter, but it will shock you through an inch of rubber shoes this is not normal electricity!

Q: Is this energy coming from the sun and being absorbed In the earth or from the center of the earth?

A: Yes, but the primary source of light ether is the sun light, yes the earth does have an economy of light ether which does follow the sun around. BUT IT IS ALSO IN THE GROUND! AND ITS IN THE AIR!

Q: Did NokolaTesla know about this in the 1900's?

A: Yes, if you read into his writings he was always saying things like, there is more energy moving than just the electricity in this stuff.

Example: If you take a large Tesla coil and fire it up, and you drive it with a van de graph generator and you put the output of that into a Tesla coil. you can throw sparks across the room! What these electrostatic machines are gathering is light ether.

Copyright 2002 - 2004 Creative Science & Research

A Very Strange and New Discovery!

While working outside on another experiment I discovered a very strange generator effect, much to my surprise, I found that by using 2 aluminum 8" disks connected to my DC volt meter and by placing both disks in a vertical position while touching the bare earth dirt, and moving one of the disks and allowing the other to be stationary I get a dc voltage positive output! This effect works with any size or shape of aluminum, we used 8" diameter disk x 1/8" thick, we found that size to work best. Also by stacking them like a capacitor you will find that the current output is far greater, For Example: see figure 1, Disk A would have 4 more disks connected in parallel of the same size separated by paper die electrics. The same goes for Disk   B .

First find a spot any where on the ground where there is no grass (best when wet). Please note, it's not just creating an acid battery effect, you are also getting a good contact with the ground as a conductor to pick up ether energy.

Now place the disks side by side, attach your DC voltmeter probes onto the disks, one negative and one positive. DC meter should be on the lowest setting, now place both disks on the ground very softly and move **disk B** and **do not move disk A** (positive.) You will notice you are getting a small amount of voltage and amperage. Now Move **disk A** and do not move **disk B.** THE POLARITY CHANGES.

The rule here is; The disk that moves is always positive. since we can get a polarity change just by moving the disks at opposite times. You can make a very simple mechanical device to get AC current from on top of the earth. Again, this is not just a chemical reaction we have done many test to prove this. You can also get a small voltage reading in dry dirt. The reason for the smaller voltage in using dry dirt is because a low conductance resistance is taking place here, keeping the system from being in contact with the earth and collecting the earth **ether energy.**

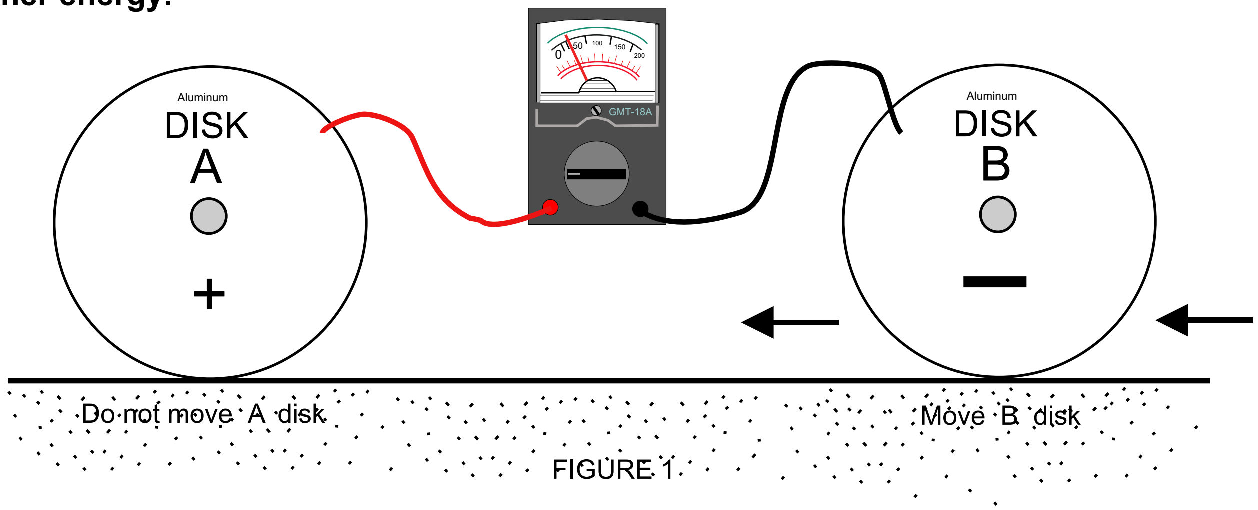


FIGURE 1

Copyright 2002 - 2004 Creative Science & Research

Capacitor Sheet Method

This method is far better than using pipes or rods. By using copper and zinc or aluminum foil sheets you will get much more amperage out of your system!

The amperage you will be collecting will be coming from 3 different sources,

1. **The acid in the ground and water**
2. **Energy that is being transmitted from the earth itself**
3. **Energy that is being transmitted from the sky and space.**

This may all seem unbelievable but it's true and is a fact! The more plates that you add the more power you will get! The copper sheet(s) is the positive, it must be facing down toward the earth. The aluminum or zinc sheet(s) is the negative and must be facing toward the sky! Between each sheet place 1- cotton or course screen printing mesh or other plastic course mesh cloth material. you can use a hole puncher to punch exact holes in each sheet, use 2 holes per sheet copper and aluminum. Use a 8 1/2" x 11" paper puncher one that is adjustable. next use a 3/4 wood base and drill hole for wood dowel rods to fit to the holes you punched in the sheets, you will have a total of 4 wood dowel rods, 2 on the right for the copper sheets and 2 on the left for the aluminum sheets to fit over, cloth die electric can be done the same. You then need to assemble dry and use another 3/4" wood board for top holding plate, which will fit over the wood dowel rods on top, sandwhich and press the assembly together and tape in place with duct tape, drill 2 long bolt holding holes on bottom wood base and top wood base then attach long bolts and nuts and tighten down. Remove tape. and attach wires, water the entire capacitor assembly and bury in the ground.

Capacitor Sheet Method

Again, the more plate sheets of metal you add (or cells) the more power you will get! Remember it's all about capacitance. You are collecting more than just simple battery type power. The copper plate sheet is the Positive + and the Aluminum sheet is the negative. There are many ways in which one can build this type of earth energy collector, below is simply an example of another shape and form. In this type we use water holes. water holes must all be in exact spots.

OUR MORE ADVANCED EARTH CAPACITOR!

(EECC) Earth Energy Coil Capacitor!

To collect more ether earth energy atoms, build the following **Earth Energy Coil Capacitor**, **Designed & Created by Creative Science & Research**. This is far better than anything we have found yet! Much more power and is easier to build.

Start with our EECC Model #1, Take a 5/16” zinc rod or aluminum rod, cut to 7.5” long. Now use #27 bare copper wire, secure it in a drill press (which you will then turn by hand). Cover zinc rod with paper one layer, use very tiny bits of tape to secure. Now apply the copper wire over the paper, remember to use copper that is not coated! Tape one end of the copper wire to the end of the zinc or aluminum rod and begin to slowly wind. Each wind must be perfectly fitted side by side, paper should be 5.5” long, total length of winds should be 4” long centered on paper. Once you are done with the first layer, apply another piece of paper to the top layer of the first copper layer, do not use to much tape to secure paper in place! Now begin your 2nd layer, repeat this same process until you have about 10 layers, (the more layers the better!) Copper must not touch the zinc or aluminum. When done hot glue or epoxy a small end piece of the copper wire so it will not come unwound. This is one complete cell, keep in mind this is a small test version, to get more power you have to THINK BIG! Build larger cells, using larger size copper. Then place them in salt water to test, 2 cells can be connected in series, after that you must connect them by use of capacitors, diodes and electronic or hand wound spring switches. If you build 20 of these and try to connect them all in series without a cap/ diode switching method, the cells will cancel each other out. Keep in mind you want water to get to each layer as well as the zinc or aluminum. You can also use Aluminum or zinc pipe.

Now concerning the paper Die Electric, Paper will not last very long, test and find a water absorbing plastic die electric,(mesh type). We suggest that you use Plastic screen mesh that you can buy at any hardware store, if all you are interested in is collecting small voltages then use one layer in between each layer of copper, if you are interested in collecting higher voltages such as lightning charges then you must use more layers of plastic screen mesh to thicken the die electric so the higher voltages will not short out your system. Paper may not last longer than 1 year, Plastic screen mesh or polyester screen printing mesh will last for many years.

EECC Model #2 Same as #1, but different. In this design we use #27 copper COATED wire, instead of bare wire. since the copper wire is coated and not bare, each layer must be sanded, that is, the top portion of the copper coated layer must be sanded off so it will be exposed to the water and acid, a die electric should still be used in this case. This type makes for a very high efficient earth cap!

EECC Model #3 Same as #1 but reversed! You will use aluminum wire and a copper rod or pipe. Use a 3/4” copper pipe and wind the die electric paper or plastic mesh and Aluminum bare wire around the copper pipe as explained in Model #1

½ size of our larger version

Winding the wire can be done quickly if you use a drill press that is redesigned and fitted with a low rpm 90 vdc conveyer belt motor with control box. www.Graingers.com

The perfect rpm is about 70 rpms, If you wish to make it a bit easier you can use larger wire such as # 17 gauge. The photo is an example of a mid size cell and can be very powerful! This is ½ size of a large cell.

Copyright 2002 - 2004 Creative Science & Research

OUR MORE ADVANCED EARTH CAPACITOR!

(EECC) Earth Energy Coil Capacitor!

Our small test model #1, we used #22 bare copper wire wrapped around a zinc rod, each layer had a paper die electric, tested in tap water. 5 layers. Output = 89 vdc x 3.5 ma, this is low. more layers will = more capacitance which ='s more amperage and voltage.

Small Drill press turned into a Coil Winder

The more layers, the more free earth energy you can collect!

Small Drill press turned into a Coil Winder. We turned this by hand. Larger coils is best to use low rpm motor at about 70 rpms, In this picture you see that we wound each wind side by side, this makes for a more high efficient earth cap. You can wild wind if you like if you use smaller wire like #31 to #34.

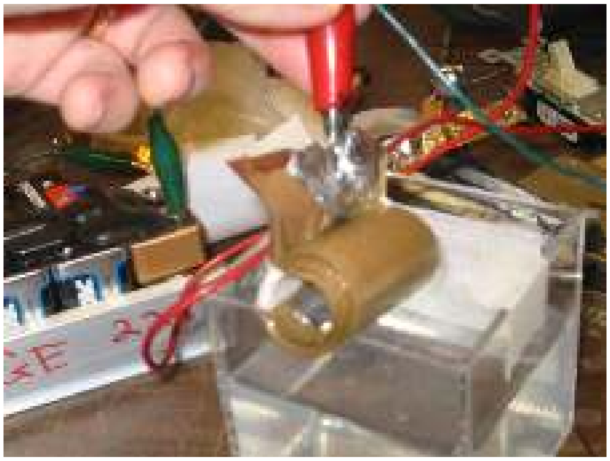
MODEL #4 Rolled Earth Capacitor

Copper foil is placed between 2 pieces of paper strips and Aluminum is placed on bottom. Use 400 foot strips 2” wide. This method is very hard to do. But is very high eff.



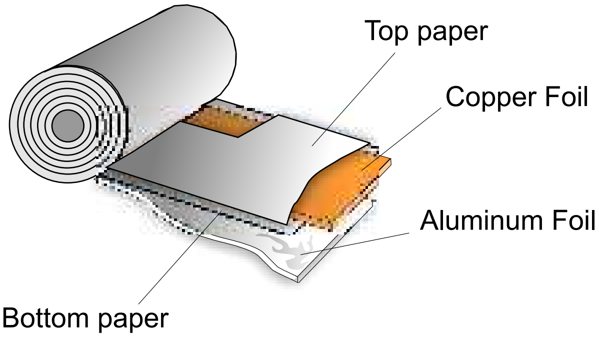
We used salt water to test rolled caps before placing them in the ground.

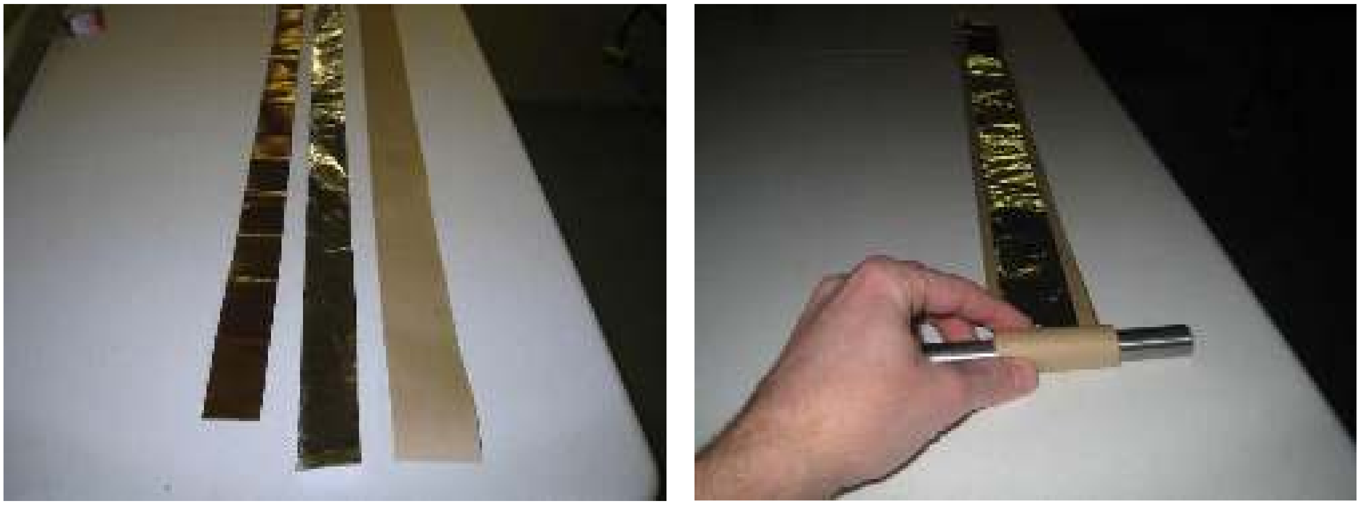
Copyright 2002 - 2004 Creative Science & Research

(EECC) Earth Energy Coil Capacitor!

MODEL #4 Rolled Earth Capacitor

Rolled Earth Capacitor

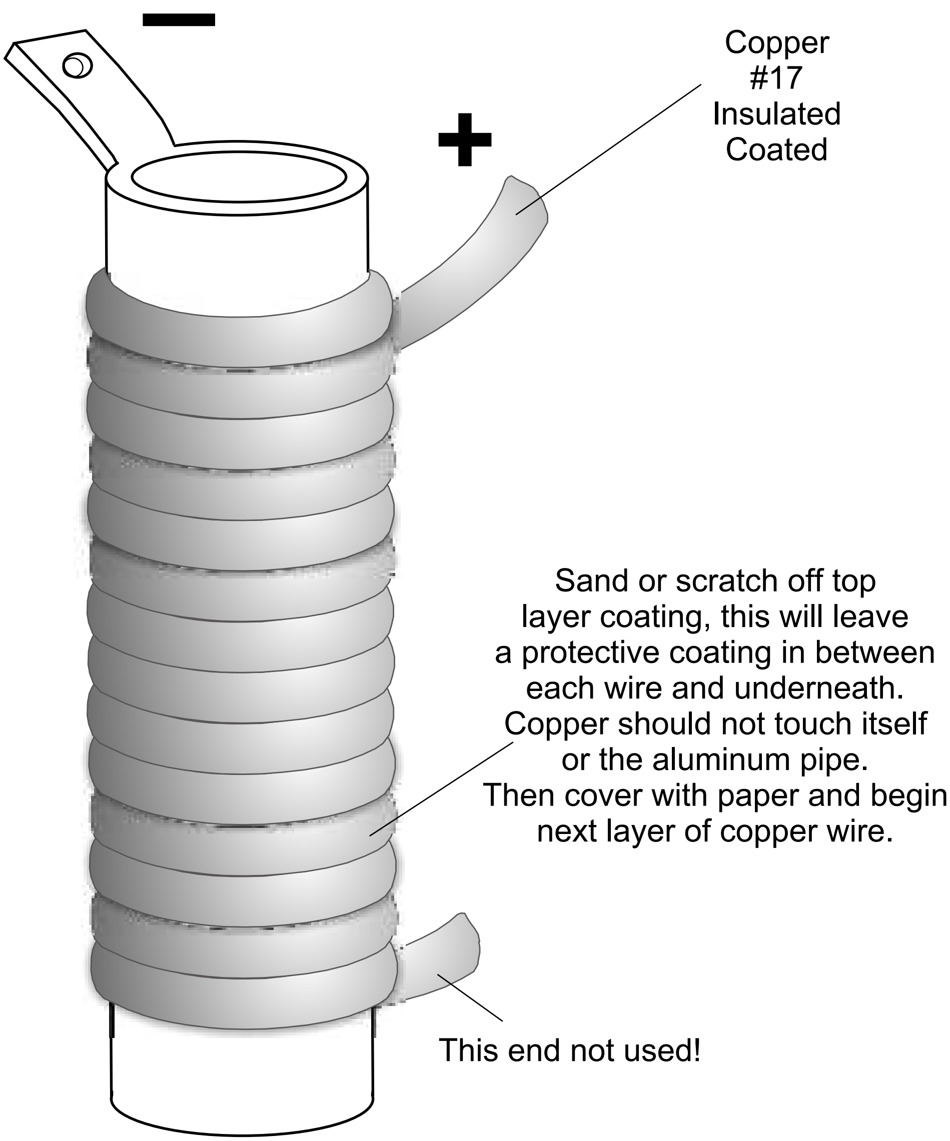




Again rolling this type of earth capacitor is very hard, Everything must be kept straight and inline with one another, Manufacturers of rolled electrolytic capacitors use computers and machinery. I am sure a simple home made roller with pin registration could be designed very easily. This type of earth battery is very high efficient. Paper is not a good die electric for high voltages! If you are wanting to collect earth and storm HV Currents you must use a thicker die electric. Metals must be spaced properly for storing high voltage.

(EECC) Earth Energy Coil Capacitor!

Rolling a capacitor is the best way but not the easiest,
Which makes this pipe coil model much more desirable to build



Sand or scratch off top layer coating, this will leave a protective coating in between each wire and underneath. Copper should not touch itself or the aluminum pipe. Then cover with paper and begin next layer of copper wire.

This end not used!

Use electrolytic capacitors to store the charge coming from each cell, then connect them in series using Commutator Sw's connected to a small rotor shaft, connected to a milliamp solar cell hobby motor or build a small fuelless engine electric motor to run on and off switch's. You can also build a very low milliamp electronic switching circuit and use the earth energy to power it. Or another more simple way would be to use a hand spring type device (timer type) glue small magnets on a long rotating rotor arm connected to the inner spring. Then place small reed relay magnetic switches, on each timing magnet ON position. should have multi reed sw's, as the unit turns if gives time for the caps to charge and then comes around and connects caps all in series which in turn discharges into main cap dump.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

DETAILED DESCRIPTION

Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this

property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than **100** volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2A-2G** using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2C** presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2D** presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2E** provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2F** presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2G** provides two supports as provided in FIG. **2F** such that at least two support members **292**, **294** may be connected to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be

placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load.

Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground.

The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

It should be emphasized that the above-described embodiments of the present disclosure, particularly, any “preferred” embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device from a plurality of support structure wires elevated above a ground level, the collection device including a carbon or graphite fiber that collects electrical enemy from the air and is electrically connected to the support structure wire; and

providing a load with an electrical connection to the plurality of support structure wires to draw current.

2. The method of claim **1**, wherein the collection device comprises a diode.

3. The method of claim **1**, wherein the collection device comprises a diode electrically connected between the fiber and the load.

4. The method of claim **1**, further comprising storing energy provided to the load.

5. The method of claim **4**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

6. The method of claim **2**, wherein the diode is elevated relative to the ground level.

7. A system of energy collection comprising:

a plurality of support structure wires elevated above ground level; at least one collection device including at least one carbon or graphite fiber that collects electrical enemy from the air and is electrically connected to the plurality of support structure wires; and

a load electrically connected to the plurality of support structure wires.

8. The system of claim **7**, wherein the collection device comprises a diode.

9. The system of claim **7**, wherein the collection device comprises a diode electrically connected between the load and the fiber.

10. The system of claim **8**, wherein the diode is elevated relative to the ground level.

11. The system of claim **7**, further comprising a diode electrically connected between the at least one collection device and the plurality of support structure wires.

12. The system of claim **7**, wherein the fiber comprises a first end and a second opposing end, and wherein the system further comprises a support structure connected to both ends of the fiber.

13. The system of claim **7**, comprising:

said at least one fiber including a plurality of collection fibers; a support frame having a top side and a bottom side; and a conducting connecting wire between the plurality of support structure wires and the support frame, wherein one end of each of a plurality of collection fibers is connected to the top side of the support frame, and the opposing end of each of a plurality of collection fibers is connected to the bottom side of the support frame.

14. The system of claim **7**, further comprising a rigid structure, the rigid structure comprising multiple supports extending outward from a single point of the support structure, wherein each end of the fiber is connected to an end of the multiple supports.

15. The system of claim **7**, further comprising a rigid structure, the rigid structure comprising multiple supports extending outward from multiple points of the support structure, wherein each end of the fiber is connected to an end of the multiple supports.

16. The system of claim **14**, further comprising a plurality of rigid structures wherein said at least one fiber includes collection fibers connected between a plurality of the rigid structures.

17. The system of claim **7**, further comprising:

a switch connected in series between the plurality of support structure wires and the load; and

a capacitor connected in parallel with the switch and the load.

18. The system of claim **17**, wherein the switch comprises an interrupter connected between the plurality of support structure wires and the load.

19. The system of claim **18**, wherein the interrupter comprises one of a fluorescent tube, a neon bulb, an AC light, or a spark gap.

20. The system of claim **18**, further comprising a transformer connected between the interrupter and the load.

21. The system of claim **7**, further comprising:

a motor for providing power the motor connected between the plurality of support structure wires and the load; and

a generator powered by the motor.

22. The system of claim **7**, wherein the load comprises a spark gap in a container of fluid, and the load is used to produce a chemical reaction.

23. The system of claim **22**, wherein the fluid comprises water and the chemical reaction comprises the production of hydrogen and oxygen.

24. The system of claim **7**, further comprising a fuel cell between the plurality of support structure wires and the load.

25. The system of claim **7**, wherein the load comprises a fuel cell.

26. The system of claim **24**, wherein the fuel cell produces hydrogen and oxygen.

27. The system of claim **24**, further comprising a diode connected between the plurality of support structure wires and the fuel cell.

28. A system of collecting energy comprising:

means for suspending carbon or graphite collection fibers, the means elevated above a ground level, the collection fibers collecting electrical enemy from the air and electrically connected to the means for suspending collection fibers;

means for inducing current flow, the means for inducing current flow electrically connected to the means for suspending collection fibers; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the collection fibers and the means for inducing current flow.

UNITED STATES PATENT OFFICE.

ANDOR PALENCSÁR, OF BUDA-PESTH, AUSTRIA-HUNGARY.

APPARATUS FOR COLLECTING ATMOSPHERIC ELECTRICITY.

SPECIFICATION forming part of Letters Patent No. 674,427, dated May 21, 1901.

Application filed July 10, 1900. Serial No. 23,102. (No model.)

To all whom it may concern:

Be it known that I, ANDOR PALENCSÁR, a subject of the King of Hungary, residing at Buda-Pesth, Austria-Hungary, have invented a certain new and useful Apparatus for Collecting Atmospherical Electricity, of which the following is a full, clear, and exact specification.

The present invention concerns an apparatus for collecting and driving or conducting atmospherical electricity which renders it practicable to obtain material quantities of the same in serviceable form.

The experiments made hitherto have been limited to deviating or conducting the electricity by simple lightning-rods without making allowance for the progress of the theory of atmospherical electricity. It is obvious that only extremely small quantities of electricity can be collected in this manner, and, moreover, it was obtained in a form which entirely precluded its utilization. It is evident that a source of electricity of irregular yield can only be utilized by means of accumulators and for charging accumulators only a current of constant potential can be employed. The potential of electricity derived or deviated by means of a lightning-rod varies within wide limits, and, moreover, it is so high that it cannot be used at all for charging accumulators. All these drawbacks are remedied by the present invention, by which the atmospheric electricity is obtained in larger quantities with as low and constant a potential as may be desired.

The idea underlying the invention is based on the modern theory of atmospheric electricity, according to which it is produced by the condensation of steam or aqueous vapors, and that the increase of potential is effected by the concentration of the small drops of water into larger ones, as the proportion of the surface of the drops to the volume of same is materially reduced thereby. According to this theory the water-droplets floating in the layers of air are considered as vehicles or carriers of the electricity, and a rational system of the deviation of the atmospheric electricity must derive it from the water-drops. This is attained by the present invention in the following manner: A collecting-body of as large a surface as possible is provided with sharp needles. This is moved in the higher layers of air, while being continually heated by a suitable heating device. Owing to the heat the water-drops immediately ambient to the collecting-body will be evaporated, their capacity is gradually reduced, while the potential of the charge grows until it reaches an infinite height with infinite smallness of the drops. It is readily apparent that the whole charge of the drops as soon as they have been evaporated will have passed to the collector or collecting-body, from which it can be conducted. For the purpose of replacing the evaporated drops, which have been deprived of their charge by new-charged drops, the collector is moved in relation to the ambient air.

One way of carrying out the invention is represented in diagram in the accompanying drawings, in which—

Figure 1 is a longitudinal section of the collecting-balloon. Fig. 2 shows the deviating and conversion device, and Fig. 3 a detail. Fig. 4 is a diagrammatic perspective view of a form of automatic regulator for the rheostatic machine.

The apparatus consists of a balloon having two walls and covered with a light wire net, preferably of aluminium wire, said net being studded with needles. Besides, the balloon carries the net 3, on which the ring 4, made of a solid but light material, (wood, cane, &c.,) is fixed. This ring carries the basket 6 by means of the cords or ropes 5. On a level with the ring 4 is the ring 7, which is kept spread by the blades or wings 9, which are journaled in a manner to rotate easily. The ring 7 is kept fixedly in position by the cords or ropes 8. The blades or wings consist of a frame covered with light material, and their rotation in either direction is limited by the stops or ledges 10. The blades or wings form advantageously an angle of sixty to seventy degrees with the vertical line.

All wire nets, ropes, rings, and blades or wings may be covered with small metal needles which are electrically connected with each other.

From the space 11, formed between the double walls of the balloon, the pipe 26 leads from the lowest point of the same to the serpentine 12, arranged in the basket 6, which in turn is

connected with the pipe 13, ending in the upper part of the space 11 between the two walls 12. The serpentine is heated by means of a suitable source of heat, whereby a warm current of gas or air circulates continually between the double walls of the balloon.

Under the basket the ball-bearing 14 is arranged in electrical connection with the wire nets, and its stud is electrically connected with the carefully-insulated light though sufficiently strong cable 15.

On the earth's surface is a winch 16, Fig. 2, by means of which the balloon can be made to ascend or descend as soon as the interior space of the balloon is filled with illuminating gas or hydrogen.

The end of the cable-core is soldered to a collector arranged upon and insulated from the axle of the winch, and the electricity is conducted from this collector by means of a sliding contact. The collecting of the electricity takes place by moving the balloon continuously up and down by means of the winch. In this movement the balloon is turned by means of the wings or blades 9, which are adapted to turn the balloon always in the same direction whether ascending or descending, as in the change from ascending into descending of the balloon, or vice versa, the blades are turned over by the aerial resistance, and thus impart the rotating motion to the balloon in the same direction. In order to avoid torsion of the cable, the ball-bearing 14 is provided. This up-and-down motion and rotating of the balloon accomplishes the purpose of bringing it into contact with as many water particles floating in the air as possible.

As the electricity conducted from the collector-wing 17 possesses a much too high and varying potential for making its direct application practicable, and as it is usual with an irregular source of electricity to first charge accumulators and to further utilize the easily-regulated current of the same only, it becomes necessary to seek to maintain the electricity conducted from the collector 17 for the charging of the accumulators at a constant potential and convert the potential to a much lower one; but as we deal in this case with a direct current ordinary converters cannot be used for this purpose. Moreover, the electricity possesses in this case a much too high potential, so that with the employment of ordinary converters the greatest part of the collected electricity would be lost again. The only practical method for this purpose is the converting by means of the Planté rheostatic machine, by which this high-voltage electricity can be transformed almost without any loss whatever. Thus the question of conversion would be solved, and only the question of maintenance of constant potential remains. This is obtained in the following manner: The rheostatic machine 18 or only a part of the plates is connected with an electrometer of any construction, the movable part of which closes a contact which eventually actuates an electromagnet which effects the switching or reversion of the rheostatic machine. After the switching of the rheostatic machine it is discharged, the potential falls to zero, (*nil*,) and the electrometer resumes its initial position, whereby the current of the electromagnet which effects the reversion is interrupted and the plates of the rheostatic machine are reconnected to potential. The machine is then ready for renewed charge and is again discharged when the determined potential is reached. This action is continually repeated as long as the apparatus is in operation.

A form of the automatic regulator for the rheostatic machine is represented in Fig. 4. 27 is the contact-cylinder of the rheostatic machine, on which, for clearness sake, only the contacts for the charging position of the condenser-plates are shown, while the contacts for the discharging position, which come into action after the contact-cylinder has been turned, are omitted. The coating of the condenser-plates is connected in electrical circuit with the stationary ball 29 and the movable ball 32 of the charge-meter 30. When the charge of the rheostatic machine rises, the ball 32, arranged on the one extremity of the lever 31, is repelled and at a certain stroke actuated by means of the fork 33, which is fastened on the ball 32, and by dipping into a mercury-cup it closes the circuit of the source of current 34. This current passes through the windings of the anchor or armature 35, fixed on the shaft of the contact-cylinder, and it also passes through the electromagnet 36. Thereby the contact-cylinder is turned by a certain angle and the rheostatic machine is thus reversed. Then if the tension decreases by discharge and the repulsion of the balls 29 32 declines so far that the contact is interrupted at 33 the spring 37 turns the contact-cylinder into its normal position and the rheostatic machine is again switched to tension. The regulation of the electrometer is effected by the adjustable weights 38 39. When larger quantities of electricity shall be derived or deviated, two rheostatic machines may operate alternately so, that while the one is being discharged the other can be charged. It is readily apparent that if the capacity of the rheostatic machine is not changed the switching or reversion by the electrometer will always take place at the same potential of the rheostatic machine, and as the number of plates, and hence the proportion of conversion, remains the same the current impulses derived or deviated from the rheostatic machine will also have the same potential.

The irregularities of the source of electricity change the interval of time in which the charges follow each other; but as long as the potential remains constant this has no injurious effect on the charge of the accumulators. The current derived. or deviated from the

rheostatic machine can be further transformed by an ordinary converter 21 22, and whenever it is sufficiently constant it can be utilized without the intervention of the accumulators. The converters can be connected or disconnected by means of the double switch 19 20 23.

24 and 25 are the conducting-wires, which run either directly to the place of consumption or to an accumulator-battery.

Having now described my invention, what I claim as new, and desire to secure by Letters Patent, is—

1. An apparatus for collecting atmospheric electricity comprising a collecting-body adapted to be kept in motion, heating means for said body, and a rheostatic machine and a converter connected with the said body electrically, substantially as described.

2. An apparatus for collecting atmospheric electricity for storage comprising a collecting-body adapted to be kept in motion in the ambient air, heating means for said body, a conductor leading from said body, a rheostatic machine connected with the said conductor, an electrometer connected with said rheostatic machine electrically, a contact controlled by the electrometer, and an electromagnet controlled by said contact, said electromagnet controlling the reversing of the rheostatic machine, substantially as described.

3. In combination, the balloon-like collecting-body, having the collecting-points, means for heating the interior space of said body, a conductor leading from the balloon-like body, and electrical devices for receiving the current therefrom, substantially as described.

4. In combination, the balloon-like collecting-body, means for turning the same constantly in one direction in both ascending and descending, conducting means leading from the balloon and electrical devices for receiving the current therefrom, substantially as described.

In witness whereof I have hereunto set my hand in presence of two witnesses.

ANDOR PALENCSÁR.

GB 157263

Process and Apparatus for Converting Static Atmospheric Electrical Energy into Dynamic Electrical Energy of any Suitable High Periodicity

Abstract -- Atmospheric electricity, utilizing; influence machines.-Static atmospheric charges are converted into alternating-currents of any desired frequency by rotary machines, the stator and rotor elements of which form condensers having a capacity which varies during the revolution as described in Specincation 157,262. In the simplest form, Fig. 2, the curved stator plates 2, 1 are connected to earth E2 and the aerial A which collects the atmospheric charges and is earthed through a safety spark gap F. The rotor is motor-driven and consists of concentric plates 3, 4 joined through slip-,rings (not shown) to an inductance 9 shunted by a condenser 5. With a given aerial polarity, rotation of the plates 3, 4 causes current reversals on the circuit A, 1, 9, 2, E@, whereby oscillations are set upon the circuit 9, 5, these being tapped by leads 11, 12. The condenser 5 may consist of concentric tubes rotating with the rotor or of two juxtaposed wound spirals having capacity. The stator and rotor condenser plates may extend over nearly a semicircle in place of the quadrants shown in Fig. 2 and the rotor may comprise two consecutive cylindrical plates or coil condensers each divided into halves, the inner half of each being connected to the outer half of the other. Fig. 7 shows a form in which rings 1, 2, mounted in a casing comprising upper and lower parts insulated from each other, are connected to the stator condenser plates at intervals. The rotor plates 3, in equal number, are connected to slip-rings 5, 6 from which alternating-current is taken by brushes when the rotor is motor-driven. The rings 1, 2 are respectively connected to the aerial collector and earth E2. Several methods of grouping the stator-rotor condenser pairs and the components of the oscillating circuit are described. The oscillatory current in the rotor circuit may react through a transformer on the main charging current and two pairs of stator and rotor plates 1, 2, 3, 4, Fig. 13, may be employed arranged on diameters at right-angles, the oscillatory circuit in this case consisting of a mutual inductance 5 having capacity and a portion of an adjustable inductance 9 in the stator earth connector E2. By suitably proportioning the stator and rotor plates, 'resonance may be established, whereby undamped waves may be produced. In the form shown in Fig. 15, for high-frequency oscillations, the aerial A and earth wire are tapped at points between the stator plates 1, 2 and condensers 16, 18 which are joined through an inductance 9. The rotor current is conveyed to the power circuit 11, 12 through transformers 10, 10<a>. The members composing the stator and rotor plates may be slotted, as shown in Fig. 8, with holes 1 for attaching them to the frame, or they may have spiral slots in their surfaces. Alternatively, they may be formed by embedding spiral wires 3 in a vulcanite mass 1 so as to give a smooth surface as shown in Fig. 11.

US 3760257
EM Wave Energy Converter

Abstract -- Electromagnetic wave energy is converted into electric power with an array of mutually insulated electromagnetic wave absorber elements each responsive to an electric field component of the wave as it impinges thereon. Each element includes a portion tapered in the direction of wave propagation to provide a relatively wideband response spectrum. Each element includes an output for deriving a voltage replica of the electric field variations intercepted by it. Adjacent elements are positioned relative to each other so that an electric field subsists between adjacent elements in response to the impinging wave. The electric field results in a voltage difference between adjacent elements that is fed to a rectifier to derive d.c. output power. The element pairs may be arranged in a two-dimensional

array to provide power conversion of randomly polarized electromagnetic waves, such as sunlight.

US 3931577
Radio Receiver Protection Arrangement

Abstract -- A receiver protection arrangement in which a voltage dependent on aerial voltage and a voltage dependent on aerial current are aggregated and applied to means responsive to a predetermined aggregate level to effectively short circuit the aerial lead. Additional means may be provided to dissipate energy in the input stage of a protected receiver to cause a reduced impedance to be reflected across the output of the protective arrangement.

Seismic Warning System Using RF Energy Monitor

Abstract -- The ambient broadband radio frequency field strength from broadcast stations is monitored (Figure 4) by periodic sampling (50, 52). A warning indication is provided if the field strength drops significantly. Drops in such field strength have been correlated empirically with the occurrence of seismic activity, usually several days later. Thus the indication serves as an early warning of an impending earthquake. In one preferred embodiment, a broadband, horizontal, very long monopole antenna (40) was connected to a rectifying and smoothing circuit (Figure 3) to provide a dc output proportional to the ambient rf field...

EM Wave Energy Converter

Abstract -- Electromagnetic wave energy is converted into electric power with an array of mutually insulated electromagnetic wave absorber elements each responsive to an electric field component of the wave as it impinges thereon. Each element includes a portion tapered in the direction of wave propagation to provide a relatively wideband response spectrum. Each element includes an output for deriving a voltage replica of the electric field variations intercepted by it. Adjacent elements are positioned relative to each other so that an electric field subsists between adjacent elements in response to the impinging wave. The electric field results in a voltage difference between adjacent elements that is fed to a rectifier to derive d.c. output power. The element pairs may be arranged in a two-dimensional array to provide

power conversion of randomly polarized electromagnetic waves, such as sunlight.

FIG. 3

US 3931577
Radio Receiver Protection Arrangement

Abstract -- A receiver protection arrangement in which a voltage dependent on aerial voltage and a voltage dependent on aerial current are aggregated and applied to means responsive to a predetermined aggregate level to effectively short circuit the aerial lead. Additional means may be provided to dissipate energy in the input stage of a protected receiver to cause a reduced impedance to be reflected across the output of the protective arrangement.

Seismic Warning System Using RF Energy Monitor

Abstract -- The ambient broadband radio frequency field strength from broadcast stations is monitored (Figure 4) by periodic sampling (50, 52). A warning indication is provided if the field strength drops significantly. Drops in such field strength have been correlated empirically with the occurrence of seismic activity, usually several days later. Thus the indication serves as an early warning of an impending earthquake. In one preferred embodiment, a broadband, horizontal, very long monopole antenna (40) was connected to a rectifying and smoothing circuit (Figure 3) to provide a dc output proportional to the ambient rf field...

POWERING ELECTRICAL DEVICES WITH ENERGY ABSTRACTED FROM THE ATMOSPHERE

Lloyd R. Crump, Silver Spring, Md.

Application March 12, 1954, Serial No. 415,986
1 Claim. (Cl. 321—2)
(Granted under Title 35, U. S. Code (1952), sec. 266)

The invention described herein may be manufactured and used by or for the Government for governmental purposes without payment to me of any royalty thereon.

This invention relates to the convenient and economical provision of power for the operation of electronic circuits and devices using transistors, and of other electrical devices having modest power requirements.

A great advantage of transistors, and a major reason for their enthusiastic reception since their introduction a few years ago, is the fact that they will operate satisfactorily with very low supply voltages and currents. One milliwatt or even less is sufficient to power a transistor in many applications. Various batteries have been developed to provide, in a minimum of space, the relatively minute amounts of power needed by transistors.

My invention provides methods and means that permit transistor circuits, and also other low-powered electrical devices, to be economically and conveniently operated without any batteries whatever, and indeed without any power supply whatever as power supplies are ordinarily conceived.

The invention centers around my discovery that it is practicable to construct operative transistor circuits that are able to abstract from the atmosphere sufficient electromagnetic energy to provide all necessary supply voltages and currents for their own operation. Circuits and devices powered according to my invention will operate indefinitely without any local power source whatever.

I have successfully constructed and demonstrated such circuits. For example, I have constructed a batteryless transistor radio receiver on which I have listened to either nearby or distant broadcast stations as desired, using either headphones or a loudspeaker; this receiver has been powered entirely by electromagnetic energy abstracted from the atmosphere.

From the successful operation of this receiver, and from other experimental work, it becomes clear that, by the methods and means of the invention, a great variety of practical and useful transistor circuits can be powered entirely by energy abstracted from the atmosphere.

Furthermore, as will become apparent below, my invention is applicable to the powering of other electrical devices requiring relatively small amounts of power.

An object of the present invention is to provide methods and means for powering transistor circuits entirely from radiofrequency energy abstracted from the atmosphere.

Another object is to provide methods and means for powering remote radio receivers, low-powered radio transmitters, and other low-powered electrical devices, with energy received by radio from a master station, so that no local power supplies are needed by the devices and so that the powering or non-powering of the remote device is under the control of the master station.

A further object is to provide methods and means for powering transistor circuits and other low-powered electrical devices with radiofrequency energy received from one or more remote radio transmitters.

Other objects, aspects, uses, and advantages of the invention will become apparent from the following description and from the drawing.

Figure 1 is a schematic diagram of a transistor radio receiver in which all necessary power is supplied by energy abstracted from the atmosphere in accordance with the invention.

Figure 2 is a schematic diagram showing a general application of the invention to provide direct-current power to a load.

Figure 3 is a schematic diagram of a system for obtaining a high energy D.-C. source at a high voltage level using energy abstracted from the atmosphere.

Referring to Figure 1, a receiving antenna **1** is connected to antenna coupling coils **2** and **3**, the other ends of which are connected to ground. A parallel resonant circuit consisting of coil **5** and capacitor **6** is coupled to coil **2**. A second parallel resonant circuit consisting of coil **7** and capacitor **10** is coupled to coil **3**. A third parallel resonant circuit consisting of coil **11** and capacitor **12** is also coupled to coil **3**.

Coil **5** and capacitor **6** are tuned to the frequency of a radio transmitter from which it is desired to receive information—for instance, an amplitude-modulated standard broadcast station. The signal received from this transmitter need not be strong. The signal is detected by diode **15** to obtain an audio-frequency information signal. This audio signal is coupled through a capacitor **16** and is amplified by a circuit that includes a transistor **17** having a base **20**, an emitter **21**, and a collector **22**. The amplified audio output of the transistor is coupled through an audio transformer **23** to an electroacoustical transducer, preferably a permanent-magnet dynamic loudspeaker **25** as shown.

The novelty of the invention lies largely in the method and means by which the necessary direct-current power is supplied to the emitter and collector circuits of transistor **17**. This method and means will now be described.

Coil **7** and capacitor **10**, and also coil **11** and capacitor **12**, are tuned to receive radio signals of relatively high strength. It does not matter whether these signals contain information. These power signals are rectified by diodes **26** and **27** to provide direct-current power that is filtered by capacitors **30** and **31**. The D.-C. power thus obtained is utilized to power the transistor **17**.

In the circuit shown, two tuned circuits (coil **7** and capacitor **10**, and coil **11** and capacitor **12**) are tuned to power signals and the D.-C. voltages obtained from each are connected in series. The tuned power circuits may be tuned to the same or different power signals. Under certain circumstances it may be desirable to use more than two tuned power circuits and to tune them to more than two power signals; in this way power can be obtained from several signals and combined. On the other hand, if a strong power signal is available, a single tuned power circuit may suffice to give the needed D.-C. power.

Even weak information signals can be received successfully. A plurality of transistor amplifier stages can be used if desired, or other circuits such as superheterodyne circuits can be used. It is merely necessary that a sufficiently strong power signal or signals be available to provide the small amount of D.-C. needed to power the transistors.

If the information signal happens to be strong, it can be used as the power signal; all of the tuned circuits (coil **5** and capacitor **6**, coil **7** and capacitor **10**, coil **11** and capacitor **12**) are tuned to the information signal.

Engineers who have observed my invention in operation have been surprised at the unexpectedly good results obtained, even with readily available power signals of quite moderate strength. For instance, sufficient power for satisfactory operation of a loudspeaker at low volumes is

readily obtained from a 5-kilowatt standard broadcast station 5 miles away, using only an indoor antenna to pick up the power signal as well as information signals. In typical operation under these conditions a D.-C. voltage of about 2.5 to 3 volts is obtained between the emitter and the collector, at a current of about 250 microamperes; D.-C. power input to the transistor is thus of the order of 0.5 to 1 milliwatt. So far as I am aware, no one has ever before discovered and demonstrated the practicability of this method of powering a radio receiver.

Because existing broadcast stations within a radius of a number of miles provide adequate power signals, the invention is readily practicable with existing power signals in almost any location in or near any city in the United States.

Although I have described a transistor radio receiver powered by my invention, it will be readily apparent that the invention is applicable to the powering of any transistor circuit using one or a number of transistors, and to the powering of other devices requiring relatively small amounts of power. For instance, sensitive electromechanical, electrochemical, or electrothermal devices can be operated by the method of the invention.

Referring to Figure 2, which shows a more general embodiment of my invention, an antenna **35** picks up radiofrequency energy from the atmosphere. This energy flows through coil **36**, which is coupled to a tuned circuit consisting of coil **37** and capacitor **40**. The radiofrequency voltage across capacitor **40** is rectified by diode **41** and filtered by a low-pass filter **46** consisting of capacitors **42** and **44** and choke coil **43**. The resulting D.-C. voltage is applied to a load **45**.

In the practice of my invention, larger amounts of power can be obtained for short periods of time by storing received energy in a suitable energy storage device. Stored energy may then be withdrawn at intervals at a more rapid rate than that at which it was received and put into the storage device. In this way the invention can be used to provide short pulses of relatively very high electrical energy. This result can be readily obtained by charging a relatively large capacitor with direct current and then discharging the capacitor rapidly into a load when desired. This rapid discharge can be initiated automatically when the voltage across the capacitor reaches a certain level, or it can be initiated when a transistor radio receiver receives a certain information signal.

Higher voltages can be obtained with the invention by means of well known devices for raising D.-C. voltages as shown in Figure 3. The D.-C. voltage output from the capacitor **44** can be used to power a low frequency transistor oscillator **52** whose A.-C. output is raised to a higher voltage level by the transformer **55**. This relatively high A.-C. voltage can then be rectified by a diode **61** and fed to a capacitor **64** to provide a high energy D.-C. source at a relatively high voltage level at the terminals **69** and **70**. If desired, energy can now be withdrawn from the capacitor **64** at intervals in short pulses of high energy at a high voltage level. Pulsed radio transmission is one of the possible uses for this form of the invention. Other uses would be to provide a single relatively powerful pulse needed to actuate an electrothermal or electromechanical device.

As has been indicated above, in many locations and particularly anywhere in or near most American cities, power signals normally present in the atmosphere are readily available for the easy and convenient practice of the invention. However, the invention also has important applications in systems in which the necessary power signal is generated and transmitted specifically for the operation of the particular system. Such systems can, for example, comprise a master station transmitting all the power that is needed for hundreds or thousands of fixed or mobile transistor receivers or other remote devices over a range of many miles. This eliminates the need for hundreds or thousands, as the case may be, of local power supplies. At the same time, such a system has the advantage that all of the remote devices can be simultaneously activated or deactivated at the will of the master station, simply by starting or stopping the transmission of the power signal. In such systems it will often be advantageous to use power signals of frequencies sufficiently high to permit the use of resonant receiving antennas of small physical dimensions for signal pickup at the remote devices. In addition to the power signal, the master station may transmit an information signal on the same or a different carrier.

Certain types of devices powered entirely by received radio waves are of course well known. The well-known "crystal set" of the early days of radio, which used a diode rectifier to demodulate an amplitude-modulated radiofrequency signal, is an outstanding example of such a device. My invention is readily distinguishable from such prior devices, however. In typical prior devices a modulated radiofrequency signal is applied to a diode to obtain unidirectional half-wave pulses whose amplitudes vary with modulation. These pulses are integrated by means of a capacitor to obtain a unidirectional signal the amplitude of which follows the audiofrequency modulation envelope. If the radiofrequency signal is received with sufficient strength the audio signal may have sufficient power to operate headphones or similar utilization device without power amplification; but the signal is utilized for its information content, rather than to supply non-information-containing power.

My invention, on the other hand, entails the utilization of received radiofrequency energy to supply power to at least one pair of circuit points (across capacitor **31** in Fig. 1, for example), such circuit points requiring power solely for its power content and not for any information or modulation it may contain. In other words, my invention entails the utilization of radiofrequency energy to supply power that would otherwise have to be supplied by batteries, generator, or other local power source.

It will be apparent that the embodiments shown are only exemplary and that various modifications can be made in construction and arrangement within the scope of the invention as defined in the appended claim.

I claim:

An electrical device for obtaining a high energy D.-C. source at a high voltage level using energy abstracted from the atmosphere, said device comprising in combination: resonant means for receiving radio waves, first rectifier means for converting said radio waves into first direct current energy, first capacitor means for storing said first direct current energy, an oscillator powered by said direct current energy, said oscillator producing an A.-C. output, transformer means for raising said A.-C. output to an increased voltage level, second rectifier means for converting the A.-C. output of increased voltage level from said transformer into second direct current energy, and second capacitor means for storing said second direct current energy.

NASA/TP—2003-21228
Low Earth Orbit Spacecraft Charging Design Guidelines

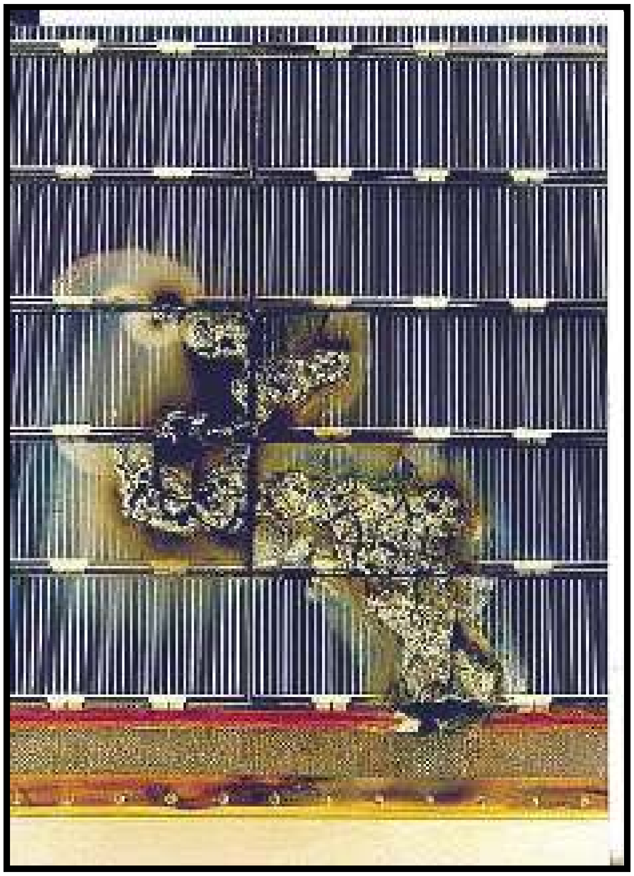
Below are a few keynote excerpts from the PDF file. The entire 367 page document is available below for those with technically savvy who want to read the entire paper...

Excerpt 1:

In the case of the TSS-1R tether, its 20 km length produced a maximum of about 3500 V potential between its most positive and negative ends, since it wasn?t oriented perfectly perpendicular to the velocity vector and the Earth?s magnetic field. A satellite at its upper end collected electrons, and an electron gun at the lower end emitted electrons to complete the circuit. When the electron gun was not in operation, a large resistance prevented the Shuttle from being biased thousands of volts negative of its surrounding plasma. However, there remained a large voltage between the tether lower end and the Shuttle orbiter. This enormous bias eventually led to a continuous arc on the tether (see The Continuous Arc, section 4.2.3.1 below), which broke, freeing the satellite and ending the experiment. During the arc, the satellite collected over 1 Amp of electron current to keep the arc going. Probe theory (Cohen et al, 19870010625 N) is usually used to calculate the total current collected by a wire with distributed potentials. However, before the break, TSS-1R demonstrated that a satellite at a high positive potential could collect an anomalously large electron current. See Zhang, et al (20000110580), Stone and Raitt (19990084046 and 20000025437), and Stone, et al (19980202347)

Excerpt 2:

Sustained arcs (continuous arcs) - These are the events that have been attributed with the destruction of on-orbit solar arrays. Generally, the process begins with a fast transient (a so-called trigger arc). Under some conditions, the transient develops into an arc that is fed directly by the entire array, effectively becoming a short-circuit. Such events invariably involve large quantities of energy and can be severely damaging to cells, interconnects or power traces.



Excerpt 3:

When the structure or array capacitance electrically connected to the arc site is sufficiently large, the initial transient arcs themselves can be large enough to produce significant damage. In Figure 9, we see an anodized aluminum plate that has undergone repeated arcing in the laboratory with the ISS structure capacitance attached. Its thermal properties have been completely destroyed, along with most of the insulating surface layer of aluminum oxide.

Excerpt 4:

The most famous sustained arc event of all led to the breakage of the TSS-1R electrodynamic tether, and the loss of the attached satellite. The image below shows the burned, frayed and broken tether end still attached to the Shuttle after the break. Incidentally, the tether continued arcing long after it and its satellite were drifting free, until finally it went into night conditions where the electron density was insufficient to sustain the arc. Noel Sargent (2002) has investigated whether the TSS-1R arc was seen to disrupt Shuttle communications. Although he has found no record of disturbed communications during the event, for most of the time the arc was shielded by metallic structures from the communications antennas, and when the tether broke, the arc was many meters from the receiving antennas. It remains to be seen whether sustained arcs produce radio noise severe enough to be a communications problem.

Comments:

This is official confirmation that the tether continued to produce plasma energy long after it broke free, accounting for the "fluorescent bulb" glowing effect viewed after. We believe this concentrated collection of plasma energy is what attracted the "swarm" of "critters" to a "feeding frenzy"

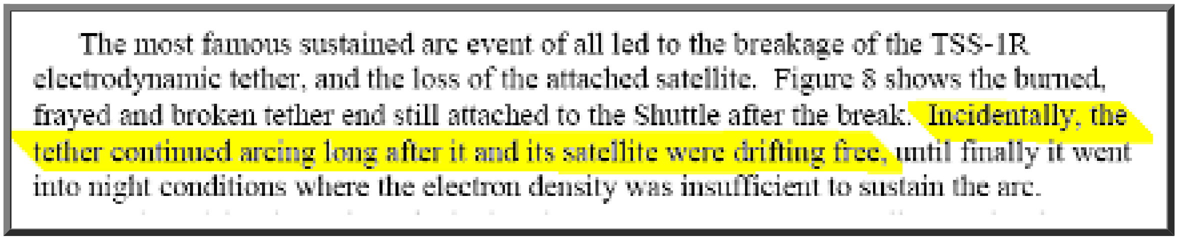
SOURCE

The Report After the Fact

...



The most famous sustained arc event of all led to the breakage of the TSS-1R electrodynamic tether, and the loss of the attached satellite. Figure 8 shows the burned, frayed and broken tether end still attached to the Shuttle after the break. Incidentally, the tether continued arcing long after it and its satellite were drifting free, until finally it went into night conditions where the electron density was insufficient to sustain the arc.

.....

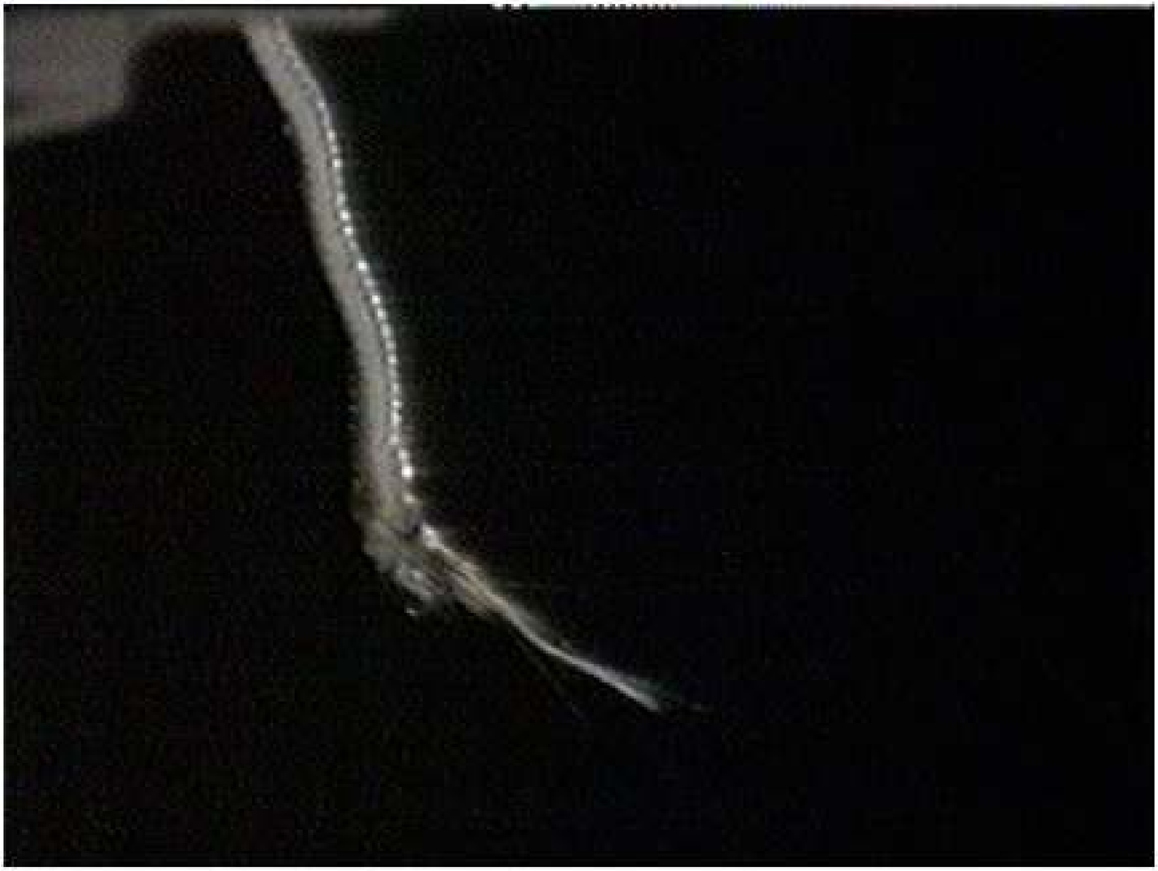


Figure 8 – The end of the remaining TSS-1R tether

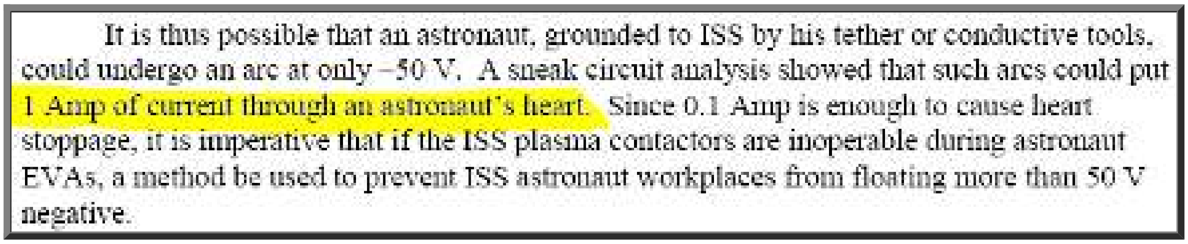
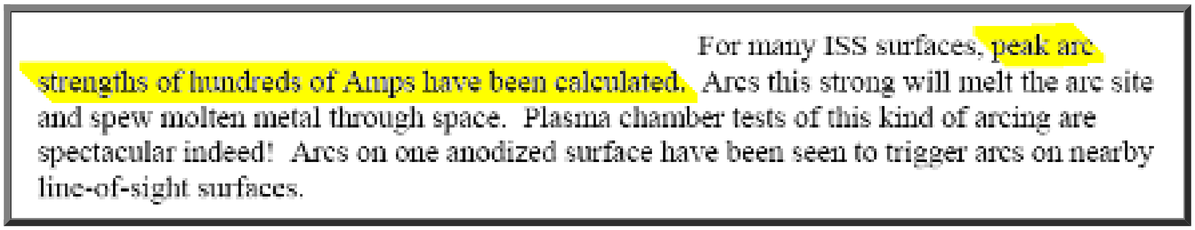
…



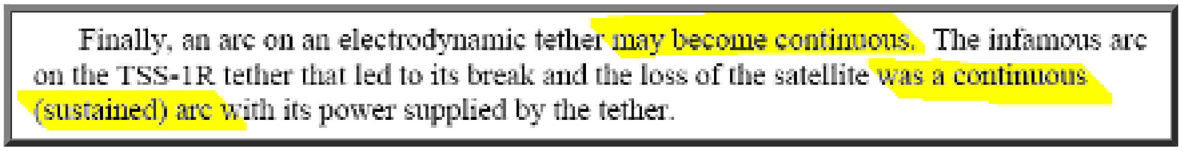
It is thus possible that an astronaut, grounded to ISS by his tether or conductive tools, could undergo an arc at only −50 V. A sneak circuit analysis showed that such arcs could put 1 Amp of current through an astronaut's heart. Since 0.1 Amp is enough to cause heart stoppage, it is imperative that if the ISS plasma contactors are inoperable during astronaut EVAs, a method be used to prevent ISS astronaut workplaces from floating more than 50 V negative.

…



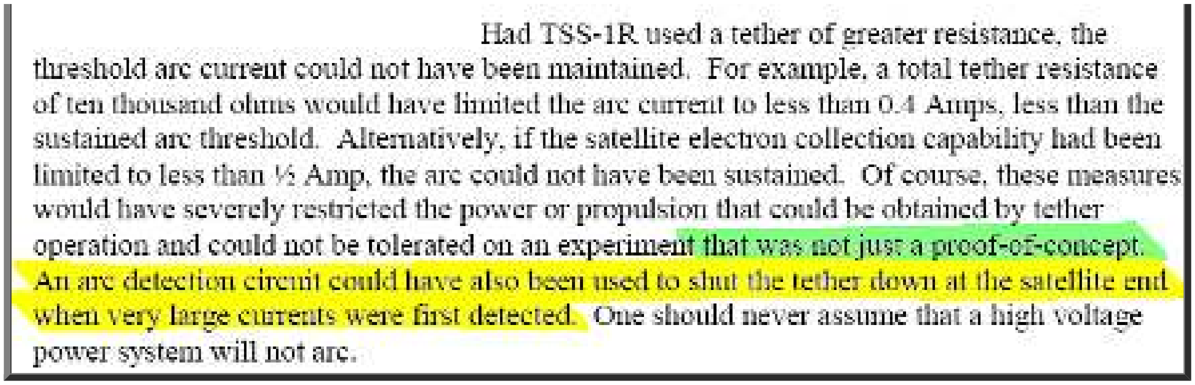
For many ISS surfaces, peak arc strengths of hundreds of Amps have been calculated. Arcs this strong will melt the arc site and spew molten metal through space. Plasma chamber tests of this kind of arcing are spectacular indeed! Arcs on one anodized surface have been seen to trigger arcs on nearby line-of-sight surfaces.

…



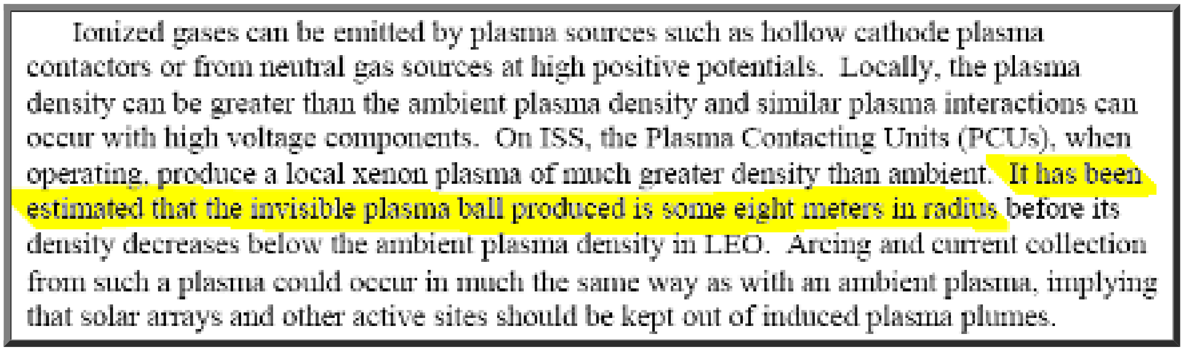
Finally, an arc on an electrodynamic tether may become continuous. The infamous arc on the TSS-1R tether that led to its break and the loss of the satellite was a continuous (sustained) arc with its power supplied by the tether.

…



Had TSS-1R used a tether of greater resistance, the threshold arc current could not have been maintained. For example, a total tether resistance of ten thousand ohms would have limited the arc current to less than 0.4 Amps, less than the sustained arc threshold. Alternatively, if the satellite electron collection capability had been limited to less than ½ Amp, the arc could not have been sustained. Of course, these measures would have severely restricted the power or propulsion that could be obtained by tether operation and could not be tolerated on an experiment that was not just a proof-of-concept. An arc detection circuit could have also been used to shut the tether down at the satellite end when very large currents were first detected. One should never assume that a high voltage power system will not arc.

…



Ionized gases can be emitted by plasma sources such as hollow cathode plasma contactors or from neutral gas sources at high positive potentials. Locally, the plasma density can be greater than the ambient plasma density and similar plasma interactions can occur with high voltage components. On ISS, the Plasma Contacting Units (PCUs), when operating, produce a local xenon plasma of much greater density than ambient. It has been estimated that the invisible plasma ball produced is some eight meters in radius before its density decreases below the ambient plasma density in LEO. Arcing and current collection from such a plasma could occur in much the same way as with an ambient plasma, implying that solar arrays and other active sites should be kept out of induced plasma plumes.

[57] **ABSTRACT**

The present invention comprises an electrodynamic tether structure and a method of use. The structure of the tether taught by the present invention is a short, wide, interconnected multiwire (compared to the long, narrow single wires of the prior art) conductive tether whose area maximizes electrodynamic drag while simultaneously minimizing the Area-Time-Product swept by the tether during its operating life. The preferred tether length is two kilometers to five kilometers. The preferred tether mass is one percent to five percent of the spacecraft mass. The method of operation comprises orienting the tether structure at an angle to the local vertical to maximize electrodynamic drag on the host spacecraft and minimize tether instability. The angle of 35.26 degrees is preferred.

FORCES AND TORQUES ON AN UPWARD DEPLOYED CONDUCTING TETHER DUE TO THE MOTION OF THE HOST SPACECRAFT THROUGH THE MAGNETIC FIELD OF THE EARTH.

FIG. 12

ELECTRODYNAMIC TETHER AND METHOD OF USE

TECHNICAL FIELD

This invention relates generally to apparatus and methods useful for changing the state vector of a space object when the space object is moving relative to a magnetic field. More specifically, the present invention relates to an apparatus and method of using a conducting tether to produce an electrodynamic force to deorbit a satellite from its orbit around a celestial body, such as the Earth, which has an associated magnetic field.

RESERVATION OF RIGHTS

This application is subject to certain rights of the U.S. government as a result of contracts between the U.S. government and the inventors.

BACKGROUND ART

The present invention has its principal utility in outer space, primarily for deorbiting satellites at the end of their useful life to mitigate the harm and reduce the liability created by the proliferation of space debris. In order to obtain a better understanding of the present invention it is helpful to understand the prior art of space tethers, especially tether dynamics and tether electrodynamics. The present invention may be more readily understood through a review of the experimental prior art and a mathematical analysis of electrodynamic space tethers.

Prior Art Tethers:

A tether was originally a rope or chain used to fasten an animal so that it grazed only within certain limits. Tethers have been used for decades in space to attach astronauts to their spacecraft.

In 1974 Professor Guiseppe Colombo, holder of the Galileo chair of astronomy at the University of Padua in Italy, proposed using a long tether to support a satellite from an orbiting platform. U.S. Pat. No. 4,097,010, which issued to Professor Colombo and Mario Grossi on Jun. 27, 1978, teaches a satellite connected by means of a long tether to a powered spacecraft. Colombo actively pursued the design of a tethered satellite system.

Several NASA experiments, such as the two Small Expendable Deployer System (SEDS 1 & 2) experiments and the Plasma Motor Generator (PMG) experiment used tethers in space. SEDS used a nonconducting tether. The PMG used a 500-meter conducting tether. The Tethered Satellite System flights in 1992 and 1996 (TSS-1 & 1R) used a 20,000-meter conducting tether.

On the TSS-1 mission the tether deployed only 260 meters (853 feet) before the deployer failed. On the TSS-1R the tether was deployed 19,500 meters. In the SEDS-2 flight, a 0.8-mm diameter, 20,000-meter long braided single-line tether was deployed to study tether dynamics and lifetime. Orbital debris or a meteoroid severed this tether in less than four days.

In the TSS-1R flight, the conducting single-line tether was severed after five hours of deployment. This failure was caused by an electric arc produced by the 3,500 volts of electric potential generated by the conductive tether's movement through the Earth's magnetic field.

The Tether Physics and Survivability (TiPS) satellite consists of two end masses connected by a 4,000-meter long non-conducting tether. This satellite was deployed on Jun. 20, 1996 at an altitude of 1,022 kilometers (552 nautical miles). Its tether is an outer layer of Spectra™ 1000 braid over a core of acrylic yarn. The yarn will "puff" its outer braid to two millimeters to "give it a larger cross section to improve its resistance to debris and small micrometeoroids", according to the National Reconnaissance Office (NRO), which is a sponsor of the TiPS mission. As of Jun. 21, 1997 the TiPS tether had survived one year.

The "Hoytether"™, an Improved, High-Reliability Tether:

In 1991, one of the present inventors, Robert Hoyt, invented a lightweight net-like structure that provides many redundant load-bearing paths. A number of primary load bearing lines running the length of the structure are connected periodically by diagonal secondary lines. The disclosed embodiment of this invention has the secondary lines firmly connected by knots to the primary lines. The secondary lines are connected only to the primary lines. At either end of the disclosed structure, a support ring enforces the cylindrical spacing between the primary lines. The secondary lines are designed with a small amount of slack. These secondary lines are only put under load if a primary line fails. This specific tether structure was disclosed to the public in 1992 (Forward, R. L., "Failsafe Multistrand Tether Structures for Space Propulsion", AIAA paper 92–3214, 28th Joint Propulsion Conference, Nashville, Tenn., 1992 (hereinafter "1992 Hoytether structure"). This structure was named a "Hoytether". The term "Hoytether" is used throughout the remainder of this specification for this type of tether structure.

The present invention uses an improved Hoytether, which was invented by the same inventors as the present invention. This improved Hoytether is the subject of a copending PCT application. The Hoytether is discussed briefly in this specification to aid understanding of the present invention.

The 1992 Hoytether design teaches that the normally slack secondary lines have half the cross-section (0.707 the diameter) of the primary lines. There are twice as many secondary lines as primary lines, thus the mass of the secondary lines is equal to the mass of the primary lines. In an undamaged Hoytether, the primary lines carry the entire load, while none of the secondary lines are under load.

While the survival probability of a single-line tether decreases exponentially with time, the Hoytether can maintain a high, i.e. greater than 99 percent, survival probability for periods of months or years (forward and Hoyt, "Failsafe Multiline Hoythther Lifetimes", Paper AIAA 95–2890, 31^{st} Joint Propulsion Conference, July 1995).

The Hoytether is essentially a tri-axial net structure, with 'primary' lines running along the length of the tether and two sets of 'secondary' lines connecting these primaries diagonally. They can be made by hand and connected with knots as is taught by the 1992 Hoytether structure. Because knotted connections severely limit the strength of a structure, it is desirable to use a knotless fabrication technique to achieve interconnections that have strengths approaching the limits of the constituent material. As these tethers may be many kilometers long; fast and inexpensive mechanical methods are required for their practical fabrication.

Hoytethers may be made by mechanical braiding, i.e. three-dimensional braiding, such as 3-D rotation braiding using braiding machines such as those developed by the Herzog Company in Germany (August Herzog Maschinenfabrik GmbH & Co., Postfach 2260.26012, Oldenburg, Germany. The specialized loom developed by the Nichimo Company of Japan (Nichimo Company Ltd., 2-6-2 Ohtemachi, Chiyoda-Ku, Tokyo, Japan) is used to produce "Ultracross" knotless fishing nets in which the individual strands are braided as a 4-braid line, and the strands are interbraided where they cross. This produces netting that has slipless interconnections that are very strong, approaching the maximum capability of the fiber. Such a loom could, with some modifications, produce the present invention's structure. Only two such machines exist, one in Japan, the other in Washington State. Unfortunately neither can work with the small line diameters needed to practice the preferred embodiment of the present invention. See generally, Ko, F. K., "Braiding", in *Engineered Materials Handbook, Vol. 1., Composites*. ASM International, Metals Park, Ohio, 1957. Pp. 519–528.

The most common 3-dimensional braiding machines are 4-step braiders based upon the designs of Maistre (German Patent P230-16986, issued 1973) and Forentine (U.S. Pat. No. 4,312,261, issued 1982). Braiding is accomplished by using pneumatics or solenoids to push the parts of the braiding machine to the proper positions. This is a slow process and making a Hoytether kilometers long with these machines would be very time consuming and expensive. The composites division of Albany International (Albany International Research Company, 777 West Street, Mansfield, Mass.) also produces a 3-D braiding machine. This machine uses modular braiding components that arc assembled breadboard fashion on a large wall.

Although braiding is the preferred technique, alternate fabrication methods such as Raschel knitting and crocheting can be used successfully. Multikilometer long Hoyththers are presently being produced for the inventors by the vendors Culzean Fabrics and Flemings Textiles using an electronically controlled crochet machine produced by Comez in Italy.

Space Tether Systems:

The prior art teaches the use of tethers in space applications. U.S. Pat. No. 5,163,641, issued on Apr. 9, 1990 to Yasaka, teaches the use of a powered spacecraft connected by a tether to a satellite. This tether is disconnected to change the state vector of the satellite. The state of the art of energy and momentum transfer using space tethers is discussed in Ivan Beckey's article "Tethering, a new Technique for Payload Deployment", Aerospace America, March 1997, at pages 36–40. Beckey concludes, "Tethers can perform the same functions as propulsive upper stages of direct payload injection, but at lower weight and cost per pound." U.S. Pat. No. 4,923,151, issued Mar. 1, 1988 to Roberts, Wilknson and Webster, teaches a tether power generator for earth orbiting satellites. U.S. Pat. No. 4,580,747, issued Mar. 15, 1983 to Pearson, teaches use of a long tether extending downward into the atmosphere from a satellite. The state vector of the satellite is changed by forces acting on a lifting body connected to the end of the tether. U.S. Pat. No. 4,824,051, issued Jan. 12, 1987 to Engelking, teaches passing an electric current through a conductive tether attached to a satellite to provide propulsive force to alter the orbit of the satellite. U.S. Pat. No. 5,082,211, issued Jan. 21, 1992 to Werka, teaches use of a tether to deorbit space debris. U.S. Pat. No. 4,727,373, issued Mar. 31, 1986 to Hoover, teaches an orbiting stereo imaging radar system having two spacecraft in synchronous parallel orbits connected by a tether.

Tether Dynamics:

In order to understand the forces that cause a tethered satellite to move upward and away from an orbiting satellite, for example, it is first necessary to explain briefly how a satellite remains in orbit. An orbiting satellite is acted on by the force of gravity which pulls it toward Earth, and by a centrifugal force, which pushes it away from Earth. The centrifugal force" (actually inertia) results from the motion of the satellite around its circular orbit. This is the same force that one can experience by swinging a ball around on the end of a string. A satellite is maintained in its orbit when it travels at the natural speed for its altitude and, as a result, the centrifugal force is equal to the gravitational force.

At the typical orbital altitude of 250 kilometers for a low-Earth orbit satellite, for example, a speed of approximately 7.6-km per second is required to create sufficient centrifugal force to balance gravitational attraction on the satellite. If the altitude is changed, the two opposing forces will no longer be in balance unless the satellite also changes its speed. A higher orbital altitude requires a slightly lower speed so the satellite will take longer to complete an orbit. Because of this, if two free-flying satellites are in orbits at different altitudes, the lower satellite will circle the Earth in less time than the satellite in the higher orbit.

If two satellites, at different altitudes, are connected to each other by a tether, they are forced to travel around their orbits together—in the same period of time, which is longer than the natural period of the lower satellite but shorter than that of the upper satellite. The lower satellite will, therefore, slow down below the natural speed for its orbit and will tend to fall to a lower orbit because the centrifugal force will now be less than the gravitational attraction of the Earth. An upward force in the tether that makes up the difference between centrifugal and gravitational forces holds it in place, however.

Correspondingly, the upper satellite will be accelerated above its natural orbiting speed (increasing its centrifugal force above the gravitational attraction) and will tend to move to a higher orbit. It, too, is held in place by an additional force (downward) in the tether. In other words, the net force downward on the lower satellite is balanced, through the tether, by the net force upward on the upper satellite. The effect of unbalanced forces on the two satellites is, therefore, to create tension in the tether. During the TSS-1 & 1R experiments, the inertia of the tethered satellite causes the satellite to rise above the orbiter as the tether is reeled out. Very close to the orbiter, there is little difference in the two orbits, and the tension force is insufficient to overcome friction in the deployer mechanism; therefore, until the satellite reaches a separation of approximately 1000-meters, the tension is augmented by small tether-aligned thrusters on the satellite. Beyond this point, the tension in the tether is the only force required.

By experimenting with a ball hung on a piece of elastic cord (a paddleball, for example) it is possible to simulate all the different types of oscillations that are possible on a space-based tether system. The elastic cord, representing the tether, may compress and stretch, causing the ball to bounce up and down (longitudinal oscillation). It also may move in a circular (skip-rope) motion or may develop wave-like motions (transverse oscillations). Even if the string itself remains straight, it is possible to get the ball swinging back and forth about its attachment point on the paddle like a child on a swing rope (pendulous motion).

Each type of motion occurs with a particular frequency, which depends on the length and tension of the tether. When the frequencies are different, the motions do not interact; however, at some tether lengths, the frequencies of two or more types of oscillation can become very close. At this point, energy can be transferred from one typc of motion to another, a phenomenon known as resonance. For instance, the transverse oscillations in the tether may cause the satellite to swing back and forth in pendulous motion.

Many different factors may cause oscillations; the movements of the satellite or Shuttle are but two of these. For an electrodynamic tether, the skip-rope and pendulous oscillations are of particular interest. If a current is passed through a tether, the current will interact with Earth's magnetic field, resulting in a force that may produce skip-rope and pendulous oscillations. Because it is necessary to maintain control of the satellite, much study has gone into identifying the different types of possible motions and the methods used to control them.

One way to control the magnitude of those motions that cause a change in tension or transverse motion at the end of the tether is to have an end mass connected to the Hoytether that maintains a controlled tension on the tether, working much like a spring-loaded 'dog leash'. This may be as simple as a coiled spring, or as complex as an active control system that measures the tension and transverse forces on the tether and adjusts the applied tension according to a local or remotely operating algorithm.

Electrodynamic Effects of Conductive Tethers:

Electric potential is generated across a conductive tether by its motion through the Earth's magnetic field. Electromagnetic forces acting on a conductive tether in orbit can make the tether system behave like an electric motor or generator, thereby exerting a useful force to alter the state vector of the tether and any mass attached to it.

Electrodynamic tether propulsion is unlike most other types of space propulsion in use or being developed for space application today—there is no hot gas expelled to provide thrust. Instead, the environment of near-Earth space is being utilized to propel a spacecraft or upper stage via electrodynamic interactions.

A charged particle moving in a magnetic field experiences a force that is perpendicular to its direction of motion and the direction of the field. When a current flows through a long, conducting tether the electrons flowing through the tether experience this force due to the fact that they are moving along the wire in the presence of Earth's magnetic field. This force is transferred to the tether and to whatever the tether is attached (like a spacecraft, satellite, space station or upper stage). It can be an orbit-raising thrust force or orbit-lowering drag force, depending upon the direction of current flow. Operation in one mode allows boost from LEO to higher orbit while reversing the current flow provides negative thrust for deboost. The principle is much the same for an electric motor; reverse its operation and it acts as a generator. The current passing through the tether is returned through the ionosphere to complete the current loop with collection and emission occurring on opposite ends of the tether.

The PMG experiment demonstrated that a conducting tether can be used as both a motor and a generator. The TSS experiments, especially TSS-1R showed that very large voltages (about 3500 volts) can be generated by a sufficiently long tether.

Uses of an electrodynamic tether as an orbit raising and lower propulsion system has many advantages over competing systems:

a. It is nearly propellantless. Most other systems expel hot gases and require extensive resupply. To emit current, the electrodynamic tether propulsion system may use plasma contactors developed as a part of the International Space Station Program. These contactors consume less than 20 kg of xenon gas per year with a 50% duty cycle. The electrodynamic tether propulsion system can also use field emitter arrays, which emit electrons without the use of any gas.

b. It can change both altitude and inclination. The Earth's magnetic field is non-uniform and can therefore provide both in- and out-of-plane forces for inclination changes as well as altitude changes. This is of particular interest to payloads requiring polar orbits in that they can be launched on a small launch vehicle into a lower inclination orbit and have it raised in space by the proper phasing of current through the tether.

A demonstration of the propulsive capabilities of electrodynamic tethers was recently approved for a flight test in 1999. The Propulsive SEDS or ProSEDS mission, will fly as a secondary payload on a Delta II launch vehicle and deploy a 5-km conducting tether using the existing SEDS deployer concept. The ProSEDS experiment will be followed by the Electrodynamic Tether Upper Stage (EDTUS) experiment that will demonstrated the use of electrodynamic forces to change both the altitude and inclination of the experimental spacecraft. FIGS. **1B** and **1C** show the calculated electrodynamic thrust at several inclinations and the reentry time sensitivity of the ProSEDS tether, respectively.

One application for long-life conducting electrodynamic tethers is as a "Terminator Tether™" for removing from orbit unwanted Earth orbiting spacecraft at the end of their useful lives. When the mission of the satellite is completed, the Terminator Tether™, weighing a small fraction of the mass of the satellite, would be deployed. The electrodynamic interaction of the conducting tether with the Earth's magnetic field will induce current flow in the tether conductor. The resulting energy loss from the heat generated by the current flowing through the ohmic resistance in the conducting tether will remove energy from the spacecraft, eventually causing it to deorbit, thus reducing the amount of orbital space debris that must be coped with in the future.

In the following analysis, it is shown that the amount of energy loss generated by an electrodynamic tether is essentially independent of its length or area, and instead is primarily proportional to the tether mass and the physical properties of the conductor metal chosen. In the typical example calculated, a 1000-kg spacecraft can be deorbited from a 1000-km high Earth orbit by a 10-kg mass tether in a month, while a 1-kg tether can deorbit a 1000-kg spacecraft in less than a year.

To the knowledge of the inventors, Joseph P. Loftus of NASA/JSC first proposed the general concept of using an electrodynamic tether to deorbit spent satellites. (Joseph P. Loftus <JLoftus@ems.jsc.nasa.gov>, personal communication via email to Robert Forward, Monday Jun. 10, 1996 15:50:10.) In order to show that the Loftus deorbit concept was not obvious to those skilled in the art of electrodynamic tethers, Forward contacted the leading expert, Joseph Carroll, of Chula Vista, Calif., who built and participated in the flight test of the PMG. After being told of the Loftus concept in a telephone conversation, his reply in an Email message dated Aug. 5, 1996, was "such a system would be feasible . . . by it is still not obvious to me that it would be useful . . . "

Loftus was considering the use of electrodynamic drag from a conducting tether to achieve this goal of bringing the unwanted spacecraft down from its high orbit (where atmospheric drag is negligible) to a 200-km orbit, where atmospheric drag would rapidly finish off the task of removing the unwanted spacecraft from orbit. The tether Loftus was considering was a single-line, conducting tether, typically 1-mm in diameter, 1-km long, and, if made of aluminum, 2-kg in mass. He would include means at the ends of the tether to contact the ambient space plasma around the Earth to complete the current loop.

Unfortunately it is probable that space impactors would sever the 1-mm diameter, 1-km long single-line tether proposed by loftus within a 1/e lifetime of four months. This would produce orbital debris rather than removing it. The motivation for this work is the NASA Safety Standard NSS 1740.14 "(Guidelines and Assessment Procedures for Limiting Orbital Debris." The relevant portion of the Standard starts on page 6-3: General Policy Objective-Postmission Disposal of Space Structures. Item 6-1: "Disposal for final mission orbits passing through LEO: A spacecraft or upper stage with perigee altitude below 2000 km in its final orbit will be disposed of by one of three methods." The method of interest is the atmospheric reentry option, Option a: "Leave the structure in an orbit in which, using conservative projections for solar activity, atmospheric drag will limit the lifetime to no longer than 25 years after completion of mission. If drag enhancement devices are to be used to reduce the orbit lifetime, it should be demonstrated that such devices will significantly reduce the area-time product of the system or will not cause the spacecraft or large debris to fragment if a collision occurs while the system is decaying from orbit."

The NASA standard applies only to NASA spacecraft and even then only to completely new spacecraft designs. New versions of existing designs are to make a "best effort" to meet the standard, but will not be required to change their design to do so. The Department of Defense has adopted the NASA standard with the same provisos. An Interagency Group report has recommended that the NASA standard be taken as a starting point for a national standard. It is NASA's recommendation to the Interagency Group that the safety requirement be phased in only as spacefaring nations reach consensus internationally, which is being done through the International Debris Coordination Working Group whose members are Russia, China, Japan, ESA, UK, India, France, Italy, and the US.

Thus, although the NASA Safety Standard in its present form is not the "Law", the existence of the standard means that some time in the future a similar requirement may be imposed on all spacecraft. This could result in major growth in future space tether business, with a sale to every non-geostationary spacecraft being "mandated" by government safety regulations, somewhat as the sale of seat belts and airbags for every car are mandated.

In fact, three of the companies planning to set up "constellations" of low to medium orbit communications: Teledesic, Iridium and Odessey have committed their companies to abide by the spirit of NASA Safety Standard 1740.14 by using one means or another to deorbit their spacecraft before they reach end of life.

Problems with Prior Art Tethers:

All electrodynamic tether designs proposed by the prior art teach that the tether should be operated at a right angle to the magnetic field through which the tether is moving. This is a problem because the electrodynamic force acting on the tether causes the tether to align itself with the magnetic field force lines. To overcome this problem the prior art teaches the use of a large ballast mass attached to the end of the tether and/or use of a very long (tens to hundreds of kilometers) tether. The large ballast mass is expensive to take to orbit because it replaces useful payload. The long tether sweeps a larger Area-Time-Product during its useful life and thus is more likely to impact other space objects, either debris or another spacecraft.

Another problem common to all proposed prior art tethers is tether instability. If the tether produces a large electrodynamic drag force, which is desirable because a large drag force will cause the satellite to deorbit quickly, then the tether will be dynamically unstable. This instability can cause the tether to lose its effectiveness, act uncontrollably and even wrap around the satellite or otherwise malfunction. Experts skilled in the art of tether design have opined that this dynamic instability is inherently unavoidable in any electrodynamic tether system. The prior art solution, such as that presently being used in the ProSEDS experiment, has been to use a large ballast mass to increase the stabilizing gravity-gradient force and/or to limit the electrodynamic drag of the tether to less that the maximum that could be produced. In the ProSEDS experiment, the conducting electrodynamic tether is five kilometers long. To insure stability, it will be augmented by a 20–35 kilometer long non-conducting tether, which to further have stability will have a 40 kilogram ballast end mass.

Yet another problem of all proposed prior art electrodynamic tether systems is how to radiate away the energy produced by the tether's operation. A satellite moving at an orbital velocity of 18,000 miles per hour has a kinetic energy of over 10,000 calories per gram. To put this amount of energy in an understandable perspective, it may be noted that when nitroglycerine explodes it produces about 1,500 calories per gram. Prior art designs of electrodynamic drag tethers teach the use of the electrical energy generated by the tether to charge batteries or operate electronics, with the excess energy being converted into heat by a resistive load. This excess heat must be radiated to the space environment or it will melt the resistive load. Thus the resistive load, and/or its associated radiator structures, must be massive and replace useful payload.

DISCLOSURE OF THE INVENTION

The present invention comprises an electrodynamic tether structure and a method of use. The principal industrial utility of the present invention is to deorbit satellites in Earth orbit at the end of their useful life. This embodiment of the present invention is sometimes referred to in this specification as a "Terminator Tether™" because it terminates the orbital lifetime of the host spacecraft. The structure of the tether taught by the present invention is a short, wide, interconnected-multiwire (compared to the long single wires of the prior art) conductive Hoytether whose area maximizes electrodynamic drag while simultaneously minimizing the Area-Time-Product swept by the tether during its operating life. The preferred tether length is two to five kilometers. The preferred tether mass is one to five percent (1%–5%) of the spacecraft mass. The method of operation comprises orienting the tether structure at a 35.26-degree trailing angle to the local vertical to maximize electrodynamic force on the tether while avoiding tether instability and allowing use of a small tether end mass.

The present invention also teaches that the satellite-tether system may be rotated around its common center of mass to centrifugally produce tension force in the tether structure to oppose forces causing tether instability. The angle of the conductive tether structure of the present invention with respect to the velocity vector of the host spacecraft may be controlled by the method of the present invention so it interacts with the encountered magnetic field to induce a maximum current flow in the tether. This produces maximum electrodynamic drag. All or a portion of this electric power may be stored and then controllably applied to the conductive tether to produce an induced electrodynamic force. This induced electrodynamic force may by used to enhance the drag force, to rotate the tether-satellite system and/or to provide satellite propulsion, i.e. to change the state vector of the satellite for any useful purpose, e.g. to avoid collision or to change the host spacecraft's orbit to an orbit more favorable for more rapid deorbiting.

The present invention also teaches a tether structure that also functions as a thermal radiator and/or plasma contactor. An embodiment of the present invention using conducting elements of the satellite, e.g. the solar arrays, as electrodynamic tether structures is also disclosed.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention may be better understood with reference to the following drawings:

FIG. **1***a* is a graph comparing the survival probability of a single line tether as taught by the prior art to the Hoytether used by the present invention.

FIG. **1***b* is a graph showing the level of electrodynamic thrust for a 10 kilometer, 10 kilowatt tether at various altitudes and inclinations.

FIG. **1***c* is a graph showing reentry time sensitivity of a five kilometer ProSEDS tether for several conditions of current flow in the electrodynamic tether.

FIGS. **2***a*, **2***b* and **2***c* show the Hoytether structure used by the preferred embodiment of the present invention.

FIG. **2***d* shows the Hoytape structure used by the preferred embodiment of the present invention.

FIG. **3** is a block electrical diagram of an electrodynamic tether system.

FIG. **4** is a graph showing a graph of the Area-Time product for three separate levels of exospheric temperature (for neutral drag calculations) and for two separate assumptions regarding tether mass and power drawn from the ambient plasma (for the Terminator Tether™ calculations).

FIG. **5** is the percent additional mass required in orbit to drop the perigee of a circular orbit at altitude, at, to a value of 200 kilometers using standard chemical rocket as taught by the prior art for deorbiting unwanted spacecraft.

FIG. **6** is a deorbit tether system shown operating with its electrodynamic tether at a trailing 35.26-degree angle to the encountered magnetic field, as is taught by the preferred embodiment of the present invention.

FIG. **7** shows an embodiment of the present invention in which the electrodynamic tether—satellite system is rotated about its center of mass to avoid tether instability.

FIG. **8** shows an embodiment of the present invention wherein the tether is powered to provide induced electrodynamic force.

FIG. **9** shows an embodiment of the present invention wherein the solar power system structure of the satellite is used as an electrodynamic tether.

FIG. **10** shows the use of a portion of the tether structure as a thermal radiator and plasma contactor.

FIG. **11** shows the braiding of an ohmic resistive load into the tether structure.

FIG. **12** is a force diagram showing the forces and torques on an upward deployed conducting tether due to the motion of the host spacecraft through the magnetic field of the Earth.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

The principal industrial utility of the present invention is the deorbiting of satellites in Earth orbit, which necessarily can happen only in outer space. Until the present invention is reduced to actual practice by use with satellites in outer space and a body of practical experience is thereby obtained, the present invention can only be constructively reduced to practice, such as by this written specification and its associated drawings, diagrams and graphs and by reference to electric measurements made on conducting tethers in space by the PMG and TSS experiments. The inventors provide herein a detailed discussion of the theory of the present invention to help those skilled in the art of aerospace and tether engineering to understand the present invention and to make and use the best embodiment of the present invention known to the inventors at the time this specification was prepared, without undue experimentation.

Although the present invention is discussed in this specification in its preferred embodiment as a means of deorbiting satellites, it must be emphasized that discussion of this specific use in no way limits the broad scope of the present invention. The present invention can be used to change the direction and speed, i.e. the state vector, of any space object providing that object is in motion relative to any magnetic field. This magnetic field may be that of the Earth or of any other celestial body, for example Jupiter or the sun.

In this specification the material forming the structure of the electrodynamic tether is specified as being a conductor. For example, a metal, such as copper or aluminum wire could be used. Likewise, nonmetallic conductor, such as carbon nanotubes, or a conductive polymer could form the conductive structure of the tether.

FIG. **1***a* shows the survival curve for a Hoytether as used by the present invention vs. the survival curve of a prior art single line tether. The survival probability curve of the Hoytether as a function of time does not conform to the well known "1/e decay" shape of a single-line tether. The Hoytether can maintain a high level of survival probability, about 99 percent, until it nears its 'lifetime'. Its survival probability then drops rapidly to zero. A detailed mathematical analysis of the difference between Hoytether and single tether survival probabilities is given in Appendix E "Small Impactor Survival Probabilities of Hoytethers" and Appendix F "Large Orbital Debris Survival Probabilities of Hoytethers", both contained in the Final Report of NASA Contract NAS8-40545. The resulting cut probability with time for the Hoytether has a "bingo curve" shapes. In a bingo game, at least five numbers must be called before anyone can win, and usually many numbers have to be called before one of the bingo cards gets five in a row. In the Hoytether at least four cuts must happen at the same level before any failure occurs, and many cuts have to be made before any one of the levels has all four lines cut. The bingo curve has the property that the probability of survival stays very high for periods short compared to the lifetime. The probability of survival is greater than 99% for periods shorter than 10% of the lifetime. This is much better performance than the 1/e curve of a single line tether, where the probability of survival is only 90% at 10% of the 1/e lifetime.

FIG. **1***b* shows the calculated level of electrodynamic thrust, in Newtons, produced by a ten kilowatt, ten kilometer single conductor tether at altitudes between 200 and 1400 kilometers and at orbital inclinations between zero degrees and eighty degrees.

FIG. **1***c* is a graph showing the reentry time sensitivity calculated for a five kilometer ProSEDS single conductor tether at altitudes between 200 and 500 kilometers with current flow in the tether between on flow and one ampere.

FIGS. **1***b* and **1***c* are the work of Enrico Lorenzini of the Smithsonian Astrophysical Observatory from his study "Performance Evaluation of the Electrodynamic Tether Tug", NASA/MSFC Grant NAG8-1303 (Nov. 12, 1966). They show that experts in the field believe that the present invention will have industrial utility, as the current flow of one ampere in FIG. **1***c* decreases the deorbit time for the calculated case from more than 180 days to less than 20 days.

FIG. **2***a* is an isometric drawing showing the generally cylindrical structure of the Hoytether. In FIG. **2***a*, primary lines **201** and **203** are shown connected via secondary lines **211**. In FIG. **2***b*, which is a schematic illustration of the structure shown in FIG. **2***a*, primary lines **201**, **203**, **205**, **207** and **209** are connected, each to their respective adjacent primary lines, by a plurality of secondary lines **221**. These connections, for example as shown at interconnection **213**, are made by knotless, slipless interconnections, such as Soutache braiding of twisted connections.

FIG. **2***c* shows the Hoytether structure of FIG. **2***b* but with a severed primary line **205** at breakpoint **215**. The second level of secondary lines **217**, shown as bold lines in FIG. **2***c*, redistribute the load from the severed primary line **215** at point **217** back to line **215** at points **219** and **221**, above and below the break, respectively.

For the electrodynamic tether, a preferred embodiment would be to unroll the tubular Hoytetherr™ into a flat Hoytape™ as shown in FIG. **2***d*.

FIG. **3** generally shows the arrangement of functional elements of an electrodynamic tether system. Of course such a system must have a means of attachment to the spacecraft, a deployer, the tether itself, some form of space plasma cathode contactor, some form of space plasma anode contactor, a power dissipation system, and a communication and control system. Each of these individual elements are known in some form to those skilled in the art of aerospace engineering. Thus the present inventors do not feel it is necessary to describe them in detail in this specification.

In FIG. **3**, a space object **301**, i.e. a satellite in Earth orbit, or any other space object either natural or man made, is physically connected to the tether system. The tether system comprises a deployer **303** from which a conductive Hoytether **305** having a bare segment **307** extends upward from space object **301**. The positively biased anode end **309** of tether **305** collects electrons from the ionosphere as space object **301** moves in direction **310** across the Earth's magnetic field. These electrons flow through the conductive structure of the Hoytether to the power system interface **311**, where it supplies power to an associated load, not shown. The electrons then flow to the negatively biased cathode **313** where electrons are ejected into the space plasma **315**, thus completing the electric circuit.

In order to allow those skilled in the art to better appreciate the broad scope of the present invention, the inventors will now provide an example using specific tether and system values to compare the Terminator Tether™ to prior art means, ie a rocket, for deorbiting a satellite.

Terminator Tethers™:

When an Earth orbiting conducting space tether moves through the magnetic field of the Earth, an electric field is generated in the tether that is proportional to the velocity of the conductor, the magnetic field strength of the Earth, and the angle between the conducting tether and the magnetic field lines. From data obtained during the various electrodynamic experiments that have been conducted in space to date, such as the PMG, TSS-1, and TSS-1R experiments, a typical value of the generated emf per unit length of tether of E=100–200 Volts/kilometer can be assumed. The electric potential V developed at the ends of a tether of length L is then V=EL. For a tether of length L=10 km, the electric potential developed is V=1000 V. For calibration, the 20-km long TSS-1R tether, at the moment of failure, was developing a potential of 3500 volts, which is 175 volts/km.

The mass of a conducting tether of length L, cross-sectional area A, and densin, d is given by m=dLA. Typical values for the density are d=2700 kg per cubic meter for aluminum and 8900-kg per cubic meter for copper. For a typical aluminum tether of mass m=10 kg and length L=10 km, the cross-sectional area will be A=0.37 mm squared. If this were a solid-wire single-line tether, the diameter of the wire would be D=0.69 mm (21.5 gauge). If this were an 18 line tubular Hoytether, the diameter of the lines in the Hoytether would be D=0.16 mm (34 gauge).

The resistance of a conducting tether of length L and cross-sectional area A is given by R=rL/A, where r is the resistivity of the conductor in nano-ohm-meters (nΩ-m). Typical values for the resistivity are r=27.4nΩ-m for aluminum and 17.0 -nΩ-m for copper. For the m=10 kg aluminum tether of length L=10 km and cross-sectional area A=0.37 mm squared at 20 degrees C, the end-to-end resistance is 750 Ω. This value of resistance is the essentially the same whether the conductor area is concentrated into a single-line tether or divided up into many lines as in a multiline Hoytether.

The current I generated in the conducting tether by the electric potential V between the ends of the tether applied across the tether resistance R is I=V/R. For the 10 kg mass aluminum tether of length L=10 km, electric potential V=EL=1000 volts, and resistance R=750 Ω the current is I=V/R=1.33 Amps. Currents near these values were measured in the TSS-1R experiment at the time of failure. At the time of failure of the TSS-1R tether, none of the plasma contactors on the Space Shuttle or the Italian Satellite were operating. Thus the current was being collected by the conductive surface area of the Space Shuttle and the Italian

Satellite at the two ends of the tether. The Space Shuttle area is quite large, so it was not the limiting factor in current collection. The diameter of the Italian Satellite was 1.6 m, which would give it an effective plasma contact area of about 8 square meters. This shows that, if the plasma contact area of the ends of a conductive space tether can be make large enough, then ampere level currents can be extracted from the ambient space plasma without the use of space plasma contactors.

The power dissipated as ohmic heating in the tether is given by P=IE. For an aluminum tether of mass m=10 kg, resistivity r=27 nΩ-m, and density d=2700 kg/cubic meter, subjected to an electric field of E=100 V/m, the power dissipated in the ohmic losses of the conductor is P=IV=1330 Watts. For a 1 kg mass tether, it would be still a considerable 133 Watts of dissipation.

There will no doubt be additional dissipation of energy in plasma ohmic losses, plasma wave generation, and plasma ion acceleration, but the ohmic losses in the conducting tether alone are sufficient for the task of deorbiting an unwanted spacecraft massing 100 to 1000 times more than the tether.

The decay time of a metric ton spacecraft moving from a 1000 km altitude orbit to a 200 km altitude orbit with an energy difference of dU=3.3GJ, when its energy is being dissipated at a power of P=1330 W by an aluminum tether massing just 10 kg, or 1% the mass of the spacecraft, is about one month. This is a remarkably short time, and indicates that the concept of using a conductive tether to deorbit a spacecraft is indeed feasible. If the aluminum tether massed only 1 kg, or 1/1000th the mass of the spacecraft it was deorbiting, then the decay time would rise to 10 months, still a reasonable value.

In reality, of course, the actual decay time will be longer than this. If the electrodynamic drag force is very large, and becomes larger than the gravity gradient forces pulling on the ends of the tether (which force is proportional to the mass of the tether), then the tether will tend to align itself along the magnetic field lines instead of across them, and the drag force will decrease because of the small angle between the conductor length and the magnetic field lines. The tether will then settle into an angle determined by the balance between these two forces.

Is the Terminator Tether™ theoretically a better means than atmospheric drag or a rocket engine for deorbiting satellites at the end of their useful life?

In the formula for da/dt (change in altitude per change in time), using the assumptions of near-circular spiral trajectories, the Area-Time-Product (Z), the criteria by which NASA judges compliance with Safety Standard 1740.14, is given by:

$$Z = A\int dt = -\frac{m}{C_D}\int\frac{da}{\rho(a)\sqrt{\mu a}},$$

where ρ(a) is simply the density as a function of semi-major axis. Thus, for a static atmosphere, the problem of area-time product is reduced to quadrature. Note that the area-time product depends only on the density profile and the ratio of spacecraft mass to drag-coefficient and is linearly related to that ratio.

The basic altitude-dependence of the atmospheric density, represented here by ρ(a) can be expressed in a low-order power series of ln(density)=f(ln(altitude)), so that it will be possible to develop a representation of the log—log relationship between altitude and density. The three static levels of atmospheric density are modeled as 5th order polynomials in the natural log of the altitude and are representative of well known atmosphere models, for example, Jacchia, L. G., "Thermospheric Temperature, Density, and Composition: New Model," SAO Special Report 375, March 1977. 2. Anon., Marshall Space Flight Center, "Long-Range Statistical Solar Activity Estimation," Atmospheric Sciences Division, 1989.) The values of exospheric temperature are reasonable (about 2-sigma) high and low solar activity values of 1400 and 800 kelvins respectively. The mean value is taken to be 1100 kevins.

FIG. **4** shows a graph of the Area-Time product for three separate levels of exospheric temperature (for neutral drag calculations) and for two separate assumptions regarding tether mass and power drawn from the ambient plasma (for the Terminator Tether™ calculations). The density profiles for the three values of exospheric temperature represent the extremes and mean values to be expected during the next several decades. The exospheric temperature goes through a cycle of about an 11 year period with maximum about 1400 kelvins and minimum about 800 kelvins.

The tether calculations include an inherent assumption that the Terminator Tether™ transfers all the energy extracted from the ambient space plasma into drag that decreases the orbital energy of the spacecraft at a rate given by the power drawn by the tether. Thus, the change in energy for a spacecraft of mass m at an initial altitude h is given by the expression:

$$\Delta E = -m\left\{\frac{\mu}{2(R_e+h)} - \frac{\mu}{2(R_e+250)}\right\},$$

and the time required to effect this change in energy of the mass, m, is just

$$\Delta t=\Delta E/P,$$

where P is the power drawn by the tether from the ambient plasma charge.

The curves for 1% and 5% tethers do not include the effects of atmospheric drag because the electrodynamic drag is orders of magnitude greater than the neutral atmospheric drag. At altitudes greater than about 700 km, the electrodynamic drag is 200 to 3000 times greater than the neutral drag forces.

It is clear, from FIG. **4** that the Terminator Tether™ concept is far superior to neutral drag in removing spacecraft from orbit, no matter how much additional area is added to the passive spacecraft to increase the atmospheric drag. The analyst should note that FIG. **4** is proportional to mass; that is, the Area-Time-Product values should be multiplied by the mass of the spacecraft and divided by 1000 kg. This is true for the neutral drag and Terminator Tether™ curves alike. The power levels assumed for the 1% and 5% tethers are only 80% of their theoretical values. This is done to provide a 20% margin on the power available from the ambient plasma and electrodynamic gradient.

Conventional rocket mechanisms can remove spacecraft from orbit, but this mechanism is apparently not viable from mass considerations when these factors are compared with the capabilities of the Terminator Tether™. A satellite owner may decide to satisfy the NASA safety requirements by adding a small solid motor and the associated hardware, software, sensors and structure to make the package independent, to be used to deorbit the spacecraft in case the main spacecraft power, attitude, or propulsion system fails.

The requirements of such a rocket motor system are more stringent than those attributed to ordinary spacecraft. The rocket motor deorbit system must operate when some or all other systems of the spacecraft have failed. These more stringent requirements are balanced by lesser requirements of performance. The backup system must simply deorbit the spacecraft; it does not have to perform all the other duties of the spacecraft. But the backup system must know when to fire under all kinds of anomalous situations, including tumbling, offset of center of mass (because of loss of parts due to collisions), and lack of knowledge of the orbital position.

FIG. **5** shows the percent additional mass required by the rocket motor system to drop the perigee of a circular orbit at some initial perigee altitude to a value of 200 km. The atmospheric drag at this 200 km perigee altitude will remove any spacecraft (in the range considered) from orbit in a few revolutions. The contours of constant stage propellant mass fraction, λ, range from low values of 0.5 through reasonable values of 0.65 to 0.7, up to the values associated with the best solid motors ($\lambda\nabla 0.93$) without adding any extra hardware to the emergency stage. An effective, independent stage to provide a retro deltaV of from 50 to 325 m/s will almost certainly have a λ of the order of 0.6 to 0.75. If the emergency stage is required to perform its own attitude determination, the stage propellant mass fraction may be as low as 0.55 or 0.50. Note that the additional mass, shown in FIG. **5**, must also be lofted to orbit in the first place, to provide the mass on orbit for the originally intended service. The stage propellant mass fraction, λ, is a key stage performance parameter that describes the ratio of the mass of propellant to the mass of the stage. That is $\lambda=m_p/(m_p+m_I)$, where m_p is the mass of the propellant and m_I is the mass of everything else in the stage (not including the payload or any stages above or below the stage being considered). Typical independent small rocket stages have values of λ from 0.60 to 0.75. The curves of stage propellant mass fraction are shown as straight lines (a minor approximation) and are included only from 0.5 to 0.95, the extremes of reasonable design practice.

These calculations that show, beyond any reasonable doubt, that the Terminator Tether™ concept is far superior to conventional mechanisms such as drag enhancement devices or small rocket deorbit propulsion systems. The superiority is measured in terms of Area-Time-Product, NASA's measure of the likelihood of collision with other spacecraft in the path of the descending spent member of a constellation. Tether calculations were made using conservative assumptions that the power extractable from the ambient plasma and electrodynamic gradient is only 80% of the theoretical power available to a perfect tether crossing the magnetic field lines at a right angle, i.e. normally.

The following analysis is presented by the inventors to help those skilled in the art to better understand the present invention when it is used as a Terminator Tether™ for removing from orbit unwanted non-geostationary Earth-orbiting spacecraft at the end their useful lives. The primary result of that analysis is that the electrical power P in the tether that is converted into heat by the resistance of the tether and radiated away into space will remove energy from the spacecraft, causing it to rapidly deorbit, thus reducing the amount of orbital space debris that must be coped with in outer space. Tether electric power P is given by:

$$P=(vB)^2m/2rd$$

where m is the mass of the conducting tether, r and d are the resistivity and density of the conducting material, and v is the velocity of the spacecraft's motion through the Earth's magnetic field B. For a m=10 kg tether of aluminum with resistivity of r=27.4 nΩ-m and density d=2700 kg/m^3, moving at a velocity v=7037 m/s relative to the Earth's horizontal magnetic field B=26.5 μT, the power dissipated is P=2350 W! This energy loss in the form of heat must necessarily come out of the kinetic energy of the host spacecraft. For a typical example, a 1000 kg spacecraft in a 1000 km high orbit subjected to an energy loss of 2350 J/s from a 10 kg tether (1% the mass of the host spacecraft) will be deorbited in a few weeks.

Power levels of the magnitude estimated in the previous paragraph have been measured in a real orbital space experiment, the TSS-1R mission carried out on the Shuttle Orbiter in 1995. In that experiment, a large Italian spacecraft, 1.6 m in diameter, was deployed upward from the Shuttle Orbiter at the end of a conducting copper wire tether covered with electrical insulation. As the tether was slowly deployed upwards, a series of measurements were made of the open circuit voltage induced in the tether by its motion through the Earth's magnetic field. The voltage between the end of the tether and the Orbiter ground varied from zero volts at the start to 3500 V when the amount of tether deployed approached its maximum length of 20 km. Periodically, the end of the tether was connected either to one of two different electron guns, which supplied contact to the surrounding space plasma, or to the Orbiter ground. The bare surfaces of the Shuttle Orbiter proved to be a surprisingly good plasma contactor via a combination of ton collection and secondary electron emission. The current flow through the tether was deliberately limited by control circuits and the current capacity of the electron guns to about 0.5 amperes, but power levels of 1800 Watts were reached.

The tether was intended to have a fully deployed length of 20 km, but at a deployed length of 19.5 km, when about 3500 V was being induced at the end of the tether inside the Orbiter reel mechanism, a flaw in the insulation allowed an electrical spark to jump in an uncontrolled manner from the tether to the Orbiter ground. With no control circuits to keep the current level down to 0.5 amperes, the current flow jumped to 1.1 amperes, and the total power generated was P=3850 Watts Most of this energy went into the electrical arc, which burned through the tether, causing it to break and halting the experiment. This experiment showed that large areas of bare conducting material, such as that provided by the 8 square meter area of the Italian spacecraft at one end of the tether and the very large surface area of the Shuttle Orbiter spacecraft at the other end of the tether, can collect and emit amperes of current, while thousands of volts of potential can be generated by sufficiently long tethers moving at orbital speeds.

Thus, both theory and experimental data collected in the space environment indicate that significant amounts of electrodynamic drag force can be obtained from a low mass conducting tether attached to a host spacecraft, provided the ends of the conductor can exchange sufficient numbers of electrons with the surrounding space plasma.

Experimental data from the TSS-1R data also produced the amazing result that the efficiency of a bare metal surface in "contacting" the space plasma is many times better than the standard theory would predict. The 8 square meters of bare surface area of the Italian spacecraft were sufficient to collect the 1.1 A of electron current. This amount of area is easily replicated by a few hundred meters of bare wire, considering that the effective collection diameter around the wire is the Debye length, which is a few centimeters at the typical values for space plasma density and temperature.

Because of this result, that a bare wire can easily collect electrons, Les Johnson, Nobie Stone, Chris Rupp, and others at NASA Marshall Space Flight Center have formed a team, which includes the present inventors, which is embarked on a new flight experiment. The experiment is scheduled for a piggy-back flight on a Delta II launch of an AF Global Positioning Satellite in early 2000. The goal of the experiment is to demonstrate that electrodynamic drag from a wire moving at orbital speeds through the Earth's magnetic field will create a large enough electrodynamic drag force to deorbit the Delta II second stage, whose mass is greater than 1000 kilograms, in a few weeks. This is essentially a demonstration of the Loftus electrodynamic drag deorbit concept and the first step in the development of a Terminator Tether™.

The ProSEDS (Propulsion Small Expendable-tether Deployer System) mission will use a 5 km long copper wire conductive tether massing 18 kg connected to a 20–35 km long nonconducting tether, which is in turn connected to a 25–40 kg ballast mass. The total of 25–40 km of tether length and the 25–40 kg ballast mass on the end will provide enough gravity gradient force to keep the tether aligned near the zenith, so that the direction of the current in the tether is at right angles to both the direction of the spacecraft motion in the nominal EW direction and the Earth's near-equatorial magnetic field in the nominal NS direction.

An important feature of the ProSEDS experiment is that it is designed to be completely self-powered. It uses a battery to initiate deployment and to power up the plasma contactor, but once current is flowing through the tether, some of the power is tapped off and used to recharge the battery. The battery, in turn, powers the current control electronics, the telemetry, system, and the plasma contactor. The ProSEDS mission will not be designed to allow ground control changes in operation, primarily because of the increase in complexity and cost associated with that option.

The present invention is the use of a small, low-mass deployer/controller package containing a large collecting area, short length, multiline space tether, such as a Hoytape mesh made of aluminum wire, as a "Terminator Tether™" for a constellation spacecraft. The Terminator Tether™ would be deployed when the host spacecraft is no longer working or no longer wanted. The electrodynamic drag from the Terminator Tether™ would rapidly remove the unwanted spacecraft from the constellation and a few weeks later complete the deorbit of the host spacecraft from space by burnup in the upper atmosphere of the Earth. For a Terminator Tether™ to be of maximum usefulness for constellation spacecraft, it would be desirable to minmize the mass and the length of the tether. A lower added mass means more mass for revenue producing transponders, while a shorter tether length means a lower collision cross-section Area-Time Product during deorbit.

FIG. **6** shows a spacecraft **600** having a state vector **602** that causes the spacecraft to move across magnetic field lines **601**. Spacecraft **600** has a conductive tether **603** attached to it by tether deployer and control system **605**. The outer end of tether **603** is attached to tether end mass **607**. Spacecraft **600** also has an attached electron emitter means **613**.

In FIG. **6**, spacecraft **600** has a velocity and direction defined by state vector **602**. As spacecraft **600** moves it causes conductive tether **603** to cut magnetic field lines **601**. As this happens the distal end of the conductive tether collects electrons, shown as arrows **611**, from the space plasma. Electrons **611** move through the conductive tether **603**, are passed through a resistive load, not shown, in control system **605**, and are emitted back into the space plasma as electrons **615** from electron emitter **613**. This produces an electrodynamic drag in the direction shown by arrow **609**.

As is discussed in detail in the electrodynamic drag analysis below, especially in that sections of the analysis titled "Optimization of Tether Angle", the maximum electrodynamic drag of the tether is achieved when the angle, shown as the Greek letter τ in FIG. **6**, is 35.26 degrees, trailing, to the direction of the magnetic field lines. This angle may be maintained by a feedback control circuit that maximizes the electrodynamic drag of the tether system, as is discussed in detail below. The tether structure **603** is a Hoytether having a length of about 2 to 5 kilometers. The use of the 35.26 degree angle to the magnetic field reduces the tether instability, allowing the use of a short tether which will have a small Area-Time-Product. This will minmize the possibility that the tether will impact another space object during its use.

In FIG. **7**, spacecraft **700** has a state vector **702** across magnetic field lines **704**. Conductive tether **706** is attached to spacecraft **700** by tether deployer and control system **708**. The distal end of tether **706** is attached to a tether end mass **710**. Spacecraft **700** has an electron emitter means **714**.

Functionally, electrons **712** flow from the space plasma into conductive tether **706**, are passed through a resistive load in control unit **708** and are emitted into the space plasma by electron emitter **714** as free electrons **716**. As is discussed in detail in the analysis below, this produces an electrodynamic drag on satellite **700**, which causes it to deorbit.

In FIG. **7**, spacecraft **700** is rotating with an angular velocity indicated by arrow **718**. This rotation causes a centrifugal force **720** to place tension on conductive tether **706**. This force **720** places tension on the tether **706** in a direction that counters tether instability. The Tether **706** may be at any angle to the magnetic field while the rotation of the tether-satellite system is producing this useful tension. FIG. **7** shows the angle to be 35.26 degrees, which is optimum, but any angle will work.

FIGS. **8***a* and **8***b* show a powered Terminator Tether™. In FIG. **8***a* the spacecraft **800** has a state vector **802** that causes it and its associated conductive tether **806** to move across magnetic field **804**. Tether **806** has an end mass **808** that is proximate a plasma contactor **810**. Just as was discussed in the embodiment of the present invention shown in FIG. **6** and FIG. **7**, an electric current moves through the circuit formed by the space plasma, the plasma contactor **810**, the conductive tether **806**, and the electron emitter **815**, thence back into the space plasma as electrons **816**. This creates an electrodynamic drag on the tether in the direction shown by arrow **818**.

In FIG. **8***b*, similar numbers indicate similar structures. In FIG. **8***b*, however, an electric power source, not shown, in spacecraft **800** provides electrons to conductive tether **806**. The electrons are emitted from the end **812** of the tether **806**. Electrons are collected to from the space plasma **814** by contactor **815**, thus completing the electric circuit. The result is an electrodynamic force on tether **806**, and therefore on spacecraft **800**, in the direction show by arrow **820**.

Spacecraft **800** in FIG. **8***b* may be rotated as is taught in the embodiment of the invention shown in FIG. **7**, above, to allow the control system to time the application of electric current to the tether **806** to cause force **820** to be exert force in any desired direction along the circle made by the rotating tether. This allows the state vector of the spacecraft to be modified to raise or lower the spacecraft's orbital altitude, or to otherwise usefully change its orbital elements.

FIG. **9** show an embodiment of the present invention wherein the conductive structure of a satellite is used as the tether. In FIG. **9**, a spacecraft **900** which has a state vector

901 and is moving across magnetic field **903**, has two attached solar panels, **902** and **904**. Solar panels **902** and **904** have conductive aluminum frames **908** and **906**, respectively. Frame **906** is electrically and mechanically connected to plasma contactor **912**. Frame **908** is electrically and mechanically connected to electron emitter **910**. As spacecraft **900** moves across magnetic field **903**, electrons from the space plasma **914** flow through contactor **912** and frame **906** to the body of spacecraft **900**, where the current flows through a resistive load, not shown, and then into frame **908** and electron emitter **910** to the space plasma **916**, thus completing the circuit. This creates an electrodynamic drag on spacecraft **900**. If the power output from solar panels **902** and **904** was directed to flow into the frames, **906** and **908**, then the electrodynamic interaction with the space plasma would cause a useful force to be impressed on spacecraft **900**, as was discussed in connection with FIG. **8** above. The spacecraft may be rotated and/or oriented to a desired angle with the magnetic field lines, as was also discussed above.

FIG. **10** shows an embodiment of the present invention wherein the plasma contactor and the resistive load are structurally part of the conductive tether. In FIG. **10** spacecraft **1000** has a state vector **1001** that causes it to pass through magnetic field **1003**. Spacecraft **1000** has a tether control and deployment system **1005** that is connected to a conductive tether **1007** having an end mass **1013**. A contactor portion **1015** of the conductive tether **1007** near end mass **1013** is adapted to contact the space plasma so as to receive or emit electrons. This may be the bare wire strands of a wide Hoytether, or it may be any other plasma contactor means that can be conveniently made electrically part of the Hoytether structure, such as points or metal fuzz. A second resistive portion **1009** of tether structure **1007** is adapted to be a resistive load. This may be done by making a portion of the tether structure from a material, such as nichrome steel wire, that has suitable electrical resistance The large surface area of the Hoytether provides an excellent radiator structure into the three degree Kelvin radiation sink of outer space.

FIG. **11** shows an alternative embodiment of the load resistance/radiator structure of the present invention. In FIG. **11**, a biline Hoytether **1002** is attached to its control and deployer system **1100** on a spacecraft, not shown, and to a tether end mass **1004**. A resistive load, **1006** is woven into the Hoytether structure, whereby this load **1006** and the section of the Hoytether **1002** into which it is woven act together as a thermal radiator allowing photons **1008** to radiate into the thermal sink of outer space.

The following detailed analysis of the present invention will help those skilled in the art to better understand and use the present invention.

Electrodynamic Drag Analysis:

The following is an optimization analysis of the electrodynamic drag produced by a conducting tether deployed from a host spacecraft that it is to deorbit. The force and torque diagram used in the analysis is shown in FIG. **12**, which shows the forces and torques on an upward deployed conducting tether due to the motion of the host spacecraft through the magnetic field of the Earth.

Physical Constants and Assumptions:

The analysis that follows will use the following physical constants and assumptions:

Newton's gravitational constant $G=6.67\times10^{-11}$ $m^3/kg\text{-}s^2$.

Mass of Earth $M_e=5.976\times10^{24}$ kg.

Radius of Earth near equator $R_e=6378$ km.

Assumed host spacecraft altitude h=622 km.

Assumed host spacecraft orbital radius a=7000 km.

Host spacecraft orbital velocity $w=\omega a=[GM_e/a\ ]^{1/2}=7546$ m/s.

Vertical gravity gradient at spacecraft $2\Gamma=2GM_e/a^3=2.32\times10^{-6}\ s^{-2}$.

Centrifugal gradient at spacecraft $\omega^2=GM_e/a^3=1.16\times10^{-6}\ s^{-2}$.

Combined gradient at spacecraft $3\Gamma=3GM_e/a^3=3\omega^2=3.49\times10^{-6}\ s^{-2}$.

Magnetic field of Earth (tilted dipole approximation):

Magnitude $B_o=35\ \mu T=0.35$ gauss.

Angle between magnetic pole and spin pole 11.5°.

Field components at spacecraft with altitude a and angle β between radius vector of spacecraft and magnetic equatorial plane.

Horizontal $B_H=B_o(R_e/a)^3\cos\beta=26.5\ \mu T\cos\beta$.

Vertical $B_V=2B_o(R_e/a)^3\sin\beta=52.9\ \mu T\sin\beta$.

Electrodynamic Tether Constants and Assumptions:

The electrodynamic tether is assumed to be made of a conducting metal, and have a length L, density d, resistivity r, and cross-sectional area A that is constant along the length of the tether. If the tether is a single round wire of diameter D, then the cross-sectional area is $A=\pi D^2/4$. Because of the micrometeorite and space debris hazard, however, it is likely the tether will be made up of redundantly interconnected multiple lines whose individual cross-sectional areas add up to A. Given these assumptions, the tether mass is then $m_T=dLA$, while the end-to-end tether resistance is $R_T=rL/A=rdL^2/m_T$.

Specific Conductivity Parameter:

The choice of the metal conductor to be used in a space tether is determined by a combination of low resistivity (high conductivity) and low density, with cost, strength, and melting point as secondary considerations for certain applications. Copper has a resistivity r=17.0 nΩ-m, a density d=8933 kg/m, and a "specific conductivity" of 1/rd=6,585 m^2/Ω-kg. Aluminum has a resistivity r=27.4 nΩ-m, which is significantly greater than that of copper, but it has a much lower density of d=2700 kg/m^3. As a result, aluminum's "specific conductivity" of 1/rd=13,500 m^2/Ω-kg is twice the conductivity per unit mass of copper. Silver, because of its higher density and higher cost, is not competitive as an electrodynamic space tether even though its resistivity of 16.1 nΩ-m is slightly better than that of copper. An alternate candidate material would be beryllium, with a resistivity r=32.5 nΩ-m, density d=1850 kg/m^3, and a "specific conductivity" of 1/rd=16,630 m^2/Ω-kg, slightly better than that of the much cheaper aluminum. Beryllium also has a higher melting point at 1551 K than aluminum at 933 K, so some of its alloys may be a preferred material for some electrodynamic applications despite its higher materials cost. Unfortunately, despite decades of metallurgical research by the nuclear power industry, highly ductile alloys of beryllium have not been found, so it is difficult to pull beryllium into wire. As a result, because of its high specific conductivity, low cost, and ready availability in ductile wire form, it will be assumed for this analysis that the electrodynamic tether will be made of aluminum wire.

Typical Resistance Values:

To be economically competitive, the mass of the tether needs to be a small fraction of the mass of the host spacecraft it is required to deorbit. Since a typical constellation spacecraft has a mass of about 1000 kg, a typical Terminator Tether™ with a mass that is 2% of the host spacecraft mass would consist of a deployer/controller package with a mass $m_D=10$ kg, containing an aluminum tether with a mass $m_T=10$ kg with a volume of $LA=m_T/d=3.70\times10^{-3}\ m^3$. If this 10 kg of aluminum were formed into a tether with a length of $L=2$ km and a cross-sectional area of $A=1.85$ mm^2, then the end-to-end resistance of the tether would be $R=rL/A=rdL^2/m_T=29.6\ \Omega$ A longer tether would have a proportionately smaller cross-sectional area and a higher resistance; for example, a 5 km long tether with the same mass would have a resistance of 185 Ω.

Orbit Inclination Assumption:

In order to make the remainder of the analysis mathematically tractable, it will be assumed that the orbit of the host spacecraft is circular and above the magnetic equator, so that the angle between the radius vector to the spacecraft and the magnetic equatorial plane is $\beta=0$ degrees. In this orbit, the velocity v of the spacecraft with respect to the magnetic field is the orbital velocity w less the rotational velocity of the magnetic field at the orbital radius a due to the once per day rotation of the Earth, or:

$$v=W-2\pi a/1\text{day}=(7546-509)\text{m/s}=7037\text{m/s}$$

This equation also shows why electrodynamic drag will not be useful for removing geostationary spacecraft from orbit. At the geostationary orbital radius of a=42,200 km, the relative velocity of the spacecraft and the rotating magnetic field of the Earth is zero.

With this assumption of an orbit above the magnetic equator, the vertical component of the Earth's magnetic field is zero and the horizontal component of the Earth's magnetic field is at right angles to both the local vertical and the direction of motion of the spacecraft. The total magnetic field seen by the host spacecraft and its Terminator Tether™ is then orthogonally horizontal and has the magnitude:

$$B=B_H=B_o[R_e/a]^3\cos\beta=26.5\mu T.$$

Where for simplicity the subscript H will be dropped for the remainder of this analysis.

This orbit, with its inclination of 11.5° with respect to the spin equator, will not stay in the plane of the magnetic equator, but will vary ±11.5° above and below it as the Earth rotates, causing a variation in magnetic field strength of ±0.5 μT, as well as a slight variation in angle. This 2% variation is negligible in terms of the other uncertainties in this analysis. It is not until the orbital inclination of the host spacecraft orbit reaches 60°, where cos 60°=0.5, that there is a significant drop in the expected magnitude of the electrodynamic drag forces calculated in this analysis.

Electromagnetic Drag Effects in Polar Orbit:

In many medium Earth orbit communication satellite constellations, there are a significant number of spacecraft at high inclinations and in nearly polar orbits. The high inclination spacecraft, with inclinations between 60° and 78.5°, will all have orbits that stay between the magnetic poles. Although the amount of electrodynamic drag will be significantly less than that experienced by spacecraft with orbits at lower inclinations, the direction of the induced electric fields in the tether will always be in the proper direction. If the tether is vertically upward, the outer tip of the tether will be positively charged and the bare wire in the tether will pull electrons out of the surrounding space plasma, while the electron emitter at the host spacecraft end will eject the electrons back into the space plasma to complete the circuit.

For spacecraft in near polar orbits with inclinations between 78.5° and 90°, however, there will be much more drastic variations. First of all, for a spacecraft in a 90° orbit that happens to pass directly over the magnetic poles, there is no horizontal component of the magnetic field when it is passing over one of the magnetic poles, so no voltage is generated in the tether during that part of the orbit, while the horizontal component of the magnetic field near the magnetic equator, while strong in magnitude, is along the spacecraft velocity vector, so no voltage is generated in the tether in that part of the orbit either. As a result, there will be negligible electrodynamic drag experienced by the host spacecraft during that particular orbit. The Earth is rotating, however, and the magnetic pole is rotating with it. A few orbits later, the host spacecraft will be passing over the Earth's spin pole at a point where the horizontal component of the magnetic field is exactly at right angles to the direction of motion of the spacecraft, so the full voltage is generated in the tether. When passing over the spin pole, the spacecraft radius vector is at an angle of 11.5° from the magnetic pole and at an angle $\beta=78.5°$ away from the magnetic equatorial plane. With these assumptions, the magnitude of the horizontal component of the magnetic field at the Earth's spin pole is a respectable:

$$B=B_o[R_e/a]^3\cos 78.5°=5.28\mu T$$

or 20% of the maximum value experiences by spacecraft orbiting above the magnetic equator. This value will drop slightly as the orbit continues, then build back up as the spacecraft passes over the opposite pole. As the Earth continues to rotate, bringing the magnetic pole again under the orbit, and the interaction of the tether with the horizontal component of the magnetic field again drops to zero. The average coupling of a tether to the Earth's magnetic field over all polar trajectories has been calculated to be 12.3 percent.

A problem experienced only by spacecraft with orbit inclinations greater than 78.5°:

The spacecraft will no longer be traveling from west to east with respect to the magnetic field axis, but will have a retrograde motion as it moves through the magnetic field. As a result, the voltage generated by the motion of the tether through the Earth's magnetic field will switch direction. The outer tip will be negatively charged and will attempt to collect ions, which is a much less efficient process than collecting electrons.

There are a number of solutions to this problem. The first is to increase the mass and length of the tether supplied to a spacecraft assigned to a polar orbit, so that higher voltages, currents, and drag are generated during the limited times the spacecraft is passing over the poles in the right direction. The second is to supply a tether with plasma contactors at both ends that can emit electrons from either end, allowing the current to flow either way, depending upon which direction the spacecraft is passing around the magnetic pole. The third is to utilize the first number of passes to torque the orbit of the spacecraft until the orbit inclination has been shifted below 60°, then turn on the electrodynamic drag full time to deorbit the spacecraft from this more favorable orbit inclination. This orbit torqueing maneuver is accomplished by activating the electrodynamic drag mechanism only when the magnetic field orientation is such that a strong out-of-plane component of force is created. This orbit torqueing maneuver can be augmented by switching to a propulsion mode, where power saved in the batteries during the drag force mode is pumped back into the tether when the magnetic field is in the opposite direction, applying electrodynamic propulsion to torque the orbit even further. With the tether at a large and stable trailing orientation, the coupling to the magnetic field can be significant to a vertical tether.

In summary, spacecraft in near-polar orbits might take longer to bring down, and might have to utilize specially designed Terminator Tethers™ that might cost and mass more than the simpler Terminator Tethers™ usable in lower inclination orbits, but a Terminator Tether™ can still remove a spacecraft from a polar orbit when desired.

The inventors now present a detailed analysis and optimization of a typical Terminator Tether™ attached to a typical host spacecraft in a typical low inclination orbit.

Electromotive Generation of Voltage and Current in the Tether:

When an object is moved at a velocity v through a magnetic field B, an electric field is generated in the frame of reference of the moving object given by:

$$E = v \times B = vB$$

where the magnetic field B of the Earth, being mostly tangent to the Earth's surface in the north-south direction, is at right angles to the velocity vector v of the spacecraft, assumed to be orbiting in a generally west-east direction. The direction of the electric field E will be at right angles to both v and B, or along the local vertical. It should be noted that this electric field exists in the moving frame of reference because a moving magnetic field creates an electric field. No object actually has to be there, but if it is, then the relative motion of the magnetic field of the Earth will not only apply magnetic forces to whatever material the object is made out of, but electric forces too.

Note also that the velocity used in this equation is the relative velocity between the object and the magnetic field. Because the Earth's magnetic field rotates with the Earth, the motion of the magnetic field must be subtracted from the orbital velocity of the object to obtain the relative velocity.

Voltage generation in a Conducting Tether:

If the moving object is a long conducting wire of length L, the electric field E, generated in the wire produces a voltage V between the opposite ends of the wire given by:

$$V = E \bullet L = EL \cos \tau = vBL \cos \tau$$

where τ is the angle between the length vector L of the tether and the electric field vector E, assumed to be in the vertical direction at right angles to the velocity vector v in the plane of FIG. **12** and the magnetic field vector B out of the plane of FIG. **12**. A typical value for the voltage level built up in a vertically oriented tether with length L=5 km and $\tau=0$, moving at a velocity of v=7037 m/s through the Earth's horizontal magnetic field of strength 26.5 μT, is 932 V, or 0.186 V/m. Spacecraft in higher inclination orbits would experience somewhat smaller electric fields. For calibration, the voltage measured between the ends of the 19.5 km long TSS-1R tether was 3500 V, or 0.175 V/m.

Contacting the Space Plasma:

Although a voltage will build up between the ends of the conducting tether, no current will flow unless the circuit is completed. The circuit cannot be completed with another wire, for it too will have a similar voltage generated in it by the moving magnetic field. Fortunately, empty space is not empty, and in near-Earth regions not too distant from the Earth's atmosphere there exists highly electrically conductive space plasma, kept partially ionized by radiation from the Sun. The electron and ion density varies from the dark to light side, with altitude, with season, with sunspot cycle, with contamination level, etc. but it typically varies from 10^{11} to 10^{13} electrons/cc.

Fortunately, it has been found that if a bare conductive surface such as the spherical Italian spacecraft in the TSS-1R experiment, or the long bare wire to be used in the ProSEDS experiment, or a multiline conducting wire Hoytape mesh, is charged to a few hundred volts, the bare conductor will readily pull electrons out of the space plasma. So all that is needed to complete a connection to the space plasma at the positively charged (upper) end of the tether is a sufficient large area of uninsulated conductor.

It is more difficult to eject electrons from a wire or to collect positive ions from the space plasma. Although it is conceivable that a very large area at the other end of the tether could collect enough ions to complete the circuit as was demonstrated during the TSS-1R mission when the Shuttle orbiter was found to be an adequate plasma contactor for over an amp of current, the present method chosen is to use an electron emitter of some sort, either a hot cathode, a plasma cathode or contactor, a field-emission device, or something similar. Once provisions have been made at both ends of the tether to allow the flow of electrons out of one end of the tether and into the other end, and the altitude of the host spacecraft is not too high, then there will be sufficient conductivity in the space plasma surrounding the host spacecraft to allow current to flow through the tether.

Current Flow In The Tether:

The amount of current I flowing through the tether depends upon the total resistance R in the circuit. This resistance will consist of three components, the effective resistance of the plasma, the resistance of the tether, calculated earlier as $R_T = rL/A = rdL^2/m_T$, and a control resistor R_C, which will be varied as needed to optimize the Terminator Tether™ performance. There will also need to be a parasitic load on the current in the form of a charging device to charge some batteries. The batteries in turn will be used to power the control and communication circuits, and drive the electron emitting devices at the negative end of the tether. A well-designed Terminator Tether™ will thus be completely self-powered, except for an initial charge in the batteries to provide electrical power for the deployment and startup procedure. For simplicity of analysis it will be assumed that this battery charging load, which absorbs power like a resistor, but which stores it and uses it later instead of dissipating it immediately as heat, is included in the control resistor R_c. Normally, this load would act as a "base resistance" below which the control resistor could not be lowered, but since the charging circuit can be turned off when desired, and operations continued without interruption using the power stored in the batteries, it will be assumed that the control resistor can be taken to near zero value in those circumstances where the space plasma conductivity is low, or the magnetic field is in the wrong orientation and the voltage being generated in the tether is not large. Under these circumstances, lowering the control resistor to near zero allows a much higher current to flow for a given generated voltage, thus increasing the power being dissipated in the tether and maintaining a high level of electrodynamic drag on the host spacecraft.

A properly designed Terminator Tether™ will have plenty of bare metal area for electron collection at the positive end, while the electron emitters at the other end are efficient in terms of emitting large electron currents at low voltages and therefore low powers, while at the same time the mass, length, and area of the conducting tether have been made such that the resistance of the tether is moderately high. Under these conditions, the effective resistance of the space plasma will be much less than the design resistance of the tether. To make the mathematics more tractable it will be assumed that the plasma resistance is can be neglected and that the voltage available to drive the tether is the full voltage generated by the moving magnetic field. Although voltage will be needed to power the electron emitter, whatever its form, it will be assumed that the required voltage and power will be supplied by the batteries. The batteries in turn will be powered by the battery charging circuit, whose effective resistance is included in the control resistor (except for those short periods when the plasma or magnetic field interactions are weak).

Given all these assumptions concerning the total resistance in the circuit, the current I flowing through the tether is then given by:

$$I=V/R=vBL\cos\tau/(R_C+rdL^2/m_T)$$

A typical current level can be estimated by assuming that the control resistance R_C should be about the same size as the tether resistance R_T, which for an aluminum tether with resistivity r=27.4 nΩ-m, density d=2700 kg/m^3, length L=5 km, and mass m_T=10 kg, is R_T=185 Ω, giving a total resistance, including the control resistance R_C, of R=370 Ω. Thus the current flowing though a tether of length L=5 km, generating a voltage of V=932 V, would be I=V/R=2.52 A.

Power Dissipation Analysis:

The induced current I flowing through the tether resistance R_T will generate heat in the wire, which will be radiated into space and lost. That radiated energy must come from somewhere. There is also power taken out of the current flow by the battery charging circuit and ultimately dissipated. In order to conform to energy conservation laws, this power and energy must come from a decrease in the total kinetic and potential energy of the host spacecraft, causing it to deorbit. Set forth below is a detailed, optimized force analysis which will calculate the drag force on the host spacecraft. In this section, by using some simplifying assumptions, it is possible to produce a general argument based on energy conservation laws, which will illustrate the broad scope of the present invention.

For this energy conservation analysis it will be assumed that the plasma resistance is small compared with the tether resistance, and that the control resistance is equal to the tether resistance:

$$R_C=R_T=rL/A=rdL^2/m_T$$

Assume that the ballast mass at the end of the tether is a large piece of the defunct host spacecraft, such as a solar panel, antenna, or battery pack, so that the gradient force is large and the tether is always oriented along the vertical so that the angle τ=0°. Also assume the spacecraft is in an orbit above the magnetic equator and thus is moving at right angles to the Earth's magnetic field, so that the angle between the orbital velocity vector and the magnetic field vector is 90°, and the electric field vector is in the vertical direction, aligned perfectly with the tether length vector. Under these ideal conditions, the voltage between the ends of the tether is given by:

$$V=E\cdot L=(v\times B)\cdot L=vBL$$

The current in the tether is then just:

$$I=V/(R_C+R_T)=vBm_T/2rdL$$

The power dissipated as ohmic heating in the tether is then given by:

$$P=IV=(vB)^2m_T/2rd$$

This equation shows the interesting result that the power dissipated does not depend upon the length or the area of the tether (within reason), but only the mass of the tether m_T, the resistivity r and density d of the tether material, and the velocity v of the conducting tether through the Earth's magnetic field B.

For a typical aluminum tether of mass m_T=10 kg, the power dissipated is an impressive P=2350 W. Even if only a small fraction of this power is dissipated in a real system, the kinetic energy of the host spacecraft would suffer a significant energy loss with time.

Orbital Energy Extraction Analysis:

The total energy U of a spacecraft of mass M in orbit around the Earth consists of two components, its positive orbital kinetic energy and its negative gravitational potential energy. If a circular orbit of altitude h and radius a=R_e+h is assumed, then the total energy of the spacecraft moving at a velocity w=$(GM_e/a)^{1/2}$ is:

$$U=+Mw^2/2-GMM_e/a=-GMM_e/2a$$

The system will be dissipating energy in the tether to decrease the energy U of the unwanted spacecraft from its relatively low negative value in a high Earth orbit to a greater negative value in a lower Earth orbit. To give a specific example, an unwanted spacecraft with a mass of M=1000 kg (a metric ton) in an orbit with an altitude of h=1000 km and a high orbital radius of a(H)=R_e+h=7371 km, then its (negative) total energy is:

$$U(H)=-GMM_e/2a(H)=-27.1\text{ GJ or }-27.1\text{ MJ/kg}$$

It is desired to lower the spacecraft to an orbit with an altitude just outside the atmosphere of h=200 km or a lower orbital radius of a(L)=R_e+h=6571 km, where atmospheric drag will finish the job. The total (negative) energy of a metric ton spacecraft at 200 km altitude is:

$$U(L)=-GMM_e/2a(L)=-30.4\text{ GJ}$$

Thus, the amount of energy needed to be dissipated in order to move the 1000 kg spacecraft from a 1000 km orbit with a total energy U(H)=−27.1 GJ down to a 200 km orbit with energy U(L)=−30.4 CJ is:

$$dU=U(H)-U(L)=3.3\text{ GJ.}$$

The decay time T of a metric ton spacecraft moving from a 1000 km altitude orbit to a 200 km altitude orbit with an energy difference of dU=3.3 GJ, when its energy is being dissipated at a power of P=2350 W by a typical aluminum tether massing just 10 kg or 1% the mass of the spacecraft, is found to be T=dU/P=16 days.

The actual decay time will be longer than this. If the electrodynamic drag force is very large, and becomes larger than the gravity gradient forces pulling on the ends of the tether, then the tether will tend to align itself along the magnetic field lines instead of across them, and the drag force will decrease because of the small angle between the conductor length and the magnetic field lines. The tether current will need to be controlled until the angle of the tether settles into an angle determined by the balance between these two forces. These electrodynamic torque vs. gradient torque dynamic interaction effects are discussed in the next section.

Force and Torque Balance Analysis:

It is now possible to calculate the forces and torques on the tether. It is also possible to use the fact that the electrodynamic and gravity forces and torques on the tether must balance each other out to calculate and teach some optimum values for some of the Terminator Tether™ parameters.

Electrodynamic Force and Torque:

As discussed above, both theory and experiment show that: provided the conducting tether is moved rapidly through the Earth's magnetic field in order to generate a voltage across it, and provided good contact is made with the space plasma, the conducting tether will have a current flowing through it. When a wire (moving or not) carrying a current I is embedded in a magnetic field B, there will be an electrodynatnic force F_E generated on each element of the wire. The electrodynamic force will be at right angles to the magnetic field vector and the length vector of the wire element, with a magnitude given by:

$$F_E=J\times B=ILB$$

where B is the horizontal component of the magnetic field, which is perpendicular to the assumed magnetic equator orbit plane, while the tether length vector L is assumed to lie in the orbit plane. If, as will be the case most of the time, the electron current is leaving the space plasma and entering the tether along the length of the tether, then IL needs to be replaced with an integral of the current along the length of the tether.

Note that the electrodynamic force amplitude or direction is not directly dependent on the motion of the tether through the Earth's magnetic field. The electrodynamic force would be the same if the tether were not moving and the current was being supplied by a battery. Since the current I is a function of the orbital velocity, however, there is a secondary dependence of the electrodynamic force magnitude on the orbital velocity, but not its direction. The electrodynamic force is always at right angles to the conductor, and stays at right angles to the conductor as the angle τ varies, as shown in FIG. **12**.

Assuming that the electrodynamic drag force is applied uniformly along the length of the tether, it is possible to make the simplifying assumption that the integrated force is effectively applied at right angles to the center of mass of the tether at the point L/2 as shown in FIG. **12**. The electrodynamic torque on the tether is then:

$$T_E=F_EL/2=IBL^2/2=vB^2L^3\cos\tau/2(R_C+rdL^2/m_T)=vB^2L^3\cos\tau/2R$$

Gravity Gradient Forces and Torques:

When a tether and its ballast end mass are deployed from a host spacecraft, the gravity gradient force field of the Earth, combined with the orbital centrifugal gradient force field, will cause the tether to deploy either up or down from the host spacecraft. The direction desired depends on which end of the tether is connected to the electron emitter. Normally, the electron emitter will be on the end attached to the host spacecraft, in which case the desired direction of deployment will be upward so that the induced voltage in the tether will produce an excess of electrons at the electron emitter end of the tether. The desired upward direction is chosen by having the deployer eject the ballast mass in the upward direction. Once the ballast mass has been started in that direction, the centrifugal force due to the orbital motion of the ballast mass will cause the ballast mass to continue to accelerate in the upward direction until it is brought to a halt by the full deployment of the tether.

If there were no electrodynamic or atmospheric drag, the equilibrium direction of the tether would be exactly along the vertical, since the combined gradient field is a maximum in that direction. Because a significant amount of electromagnetic drag is expected, the actual angle of the tether with respect to the local vertical will be at some angle τ, lagging behind the spacecraft motion in the plane of the orbit, as shown in FIG. **12**. In the following analysis shows that there is an optimum angle for τ that produces the largest electrodynamic drag force on the host spacecraft without producing tether instability.

The combined vertical gravity gradient and centrifugal gradient field 3Γ acting on the ballast mass m_B at the end of the tether of length L will produce a gradient force F_{GB} given by:

$$F_{GB}=-3_\Gamma m_BL\cos\tau$$

The strength of the force depends not only on the ballast mass m_B and the strength of the gradient field 3Γ, but also the component along the radial direction of the distance of the ballast mass from the center of mass, which is L cos τ. This force acts in the vertical direction along the radius vector leading from the ballast mass away from the center of the Earth. The amount of gradient force is not large. For a ballast mass of m_B=10 kg and a tether length of L=5 km, the gradient force is about 0.175 N.

As can be seen in FIG. **12**, the component of this gradient force that is at right angles to the tether, given by $F_{GB}\sin\tau$, will produce a torque T_{GB} on the tether that tends to restore the tether toward the vertical, lessening the angle τ.

$$T_{GB}=LF_{GB}\sin\tau=-3_\Gamma m_BL^2\sin\tau\cos\tau$$

The tether mass m_T also contributes to the gradient force and torque. If it is assumed that the tether has a uniform cross section, then it is possible to replace the distributed mass of the tether with an equivalent point mass m_T placed at the center of mass of the tether, which is the point L/2 along the tether, and a distance L/2 cos τ in the radial direction. The gradient force due to the tether mass is then:

$$F_{GT}=-3/2_\Gamma m_TL\cos\tau$$

While the gradient torque is:

$$T_{GT}=-L/2F_{GT}\sin\tau=-3/4_\Gamma m_BL^2\sin\tau\cos\tau$$

The total gradient torque attempting to restore the tether to its vertical orientation is then:

$$T_G=T_{GB}+T_{GT}=3_\Gamma(m_B+m_T/4)L^2\sin\tau\cos\tau$$

It is important to notice the variation of the total gravity gradient torque as the tether angle τ is varied. Since the gradient force is always in the radial or vertical direction, there is no torque on the tether when the tether is vertical, as is the case when there are no aerodynamic or electromagnetic drag forces. Once the drag forces become important and start to apply torque to the tether, increasing the tether angle τ, those drag torques causing an increase in tether angle τ will be opposed by a rising gradient torque which will attempt to decrease the tether angle. For small tether angles, the gradient torque increases first linearly with τ, then as sin τ, since cos τ is near unity for small τ, then at τ=45° the gradient torque reaches its maximum, where sin τ=cos τ=0.707 and sin τ cos τ=0.50. When this angle is reached, the tether is a point of catastrophic instability, for if there is a further increase in the electrodynamic drag force, causing the angle τ to become greater than 45°, the gradient torque, instead of growing stronger to counteract the increased drag torque, will become weaker and the tether angle will go rapidly to 90°.

To restore control to the tether angle if the instability occurs, it will be necessary to turn off the electrodynamic drag forces by shutting off the current flow through the tether. The τ=90° position for the tether and ballast mass is a gravitationally unstable orientation. After a time, slight fluctuations in the gravity field will allow the gradient force to slowly take over and restore the tether to the vertical orientation, which, unless it can be controlled in some way, is equally likely to be up or down. It would therefore be desirable to maintain control of the tether angle so as to avoid the tether angle getting into the region of instability.

Torque Balance on the Tether:

The angle τ of the tether is determined by a balance between the electrodynamic torque T_E attempting to increase the angle τ and the gradient torque T_G attempting to decrease the angle τ. Balance is achieved when the two torques are equal:

$$T_E=T_G=T_{GB}+T_{GT}$$

or:

$$vB^2L^3\cos\tau/2R=3\Gamma(m_B+m_T/4)L^2\sin\tau\cos\tau$$

Simplifing and rearranging yields an equation giving us the angle τ at which torque balance occurs:

$$\tau=\arcsin[vB^2L/6\Gamma(m_B+m_T/4)R]$$

The physical interpretation of this equation is that the maximum electrodynamic force that can be sustained on the tether is limited by the gradient force on the tether. It is possible to increase the electrodynamic force by decreasing the total resistance R of the tether (for example, by using a tether with a larger mass and a lower tether resistance), but if the tether resistance is too low, then the quantity in brackets becomes greater than unity and this equation has no solution, indicating that the tether has reached an angle where instability sets in.

To maintain control of the tether angle, it will be necessary to vary the control resistance of the tether to compensate for variations in magnetic field strength and direction, plasma density (which affects the plasma resistance), and other factors, and thereby maintain the tether at an intermediate angle where both the electrodynamic and gradient forces are at an appreciable level and balance each other.

Optimization of Tether Angle:

At first glance, it might seem that the optimum angle for the tether would be 45°, since at that angle the gradient torque is largest and therefore can counteract a larger electrodynamic drag force. However, since the 45° angle is the point where instability sets in, it is desirable to set the tether angle at some value below 45°. The optimum angle is that which maximizes the horizontal or drag component of the electrodynamic force. This optimum angle τ is derived from the equation for the horizontal component of the electrodynamic force, or the electrodynamic drag force, since it opposes the host spacecraft motion:

$$F_{ED}=F_E\cos\tau=6[m_B+m_T/4]\Gamma L\sin\tau\cos^2\tau$$

By setting the partial derivative$\square F_{ED}/\square\tau=0$ and solving, it is possible to calculate that the optimum angle for the tether that gives the maximum electrodynamic drag force F_{ED}, while still keeping the tether torques balanced and under control, is $\tau=\arctan(0.707)=35.26°$. With this angle selected and maintained by varying the control resistor R_C to compensate for variations in plasma contact resistance and variatins in the strength and direction of the Earth's magnetic field B seen at the spacecraft, the tether experience the maximum stable value for the electromagnetic drag force of:

$$F_{ED}(\max,\tau=35.26°)=2.31[m_B+m_T/4]\Gamma L$$

There are many ways to provide the sensing information needed to provide the feedback signals to the control resistor, but the simplest is to merely measure the drag acceleration on the host spacecraft with a set of accelerometers, and maximiize the force in the direction opposite to the host spacecraft motion. Another method would be to measure the current in the tether, and knowing the tether resistance and the amount of control resistance, calculate the power being extracted and maximize that value. Alternate methods would be to use an optical position sensor or GPS receivers at both ends of the tether to measure the angle of the tether or the position of the ballast mass with respect to the host spacecraft.

To make an estimate of the magnitude of drag force attainable, assume that a typical aluminum tether with a length of L=5 km, a tether mass of m_T=10 kg and a ballast mass of m_B=10 kg is being used. Then the maximum gradient force limited electrodynamic drag force is F_{ED}= 0.167 N. The power being dissipated in the canoical tether at the angle τ, with $R_C=R_T=rdL^2/m_T=185\ \Omega$ is given by:

$$P=IR=[vBL\cos\tau]^2(R_C+rdL^2m_T)$$

which for an angle $\tau=35.26°$ results in a power dissipation of 1570 W. Thus, the thrust level per unit power obtained by the typical Terminator Tether™ would be about 0.106 N/kW. This number is comparable to the value of 0.148 N/kW estimated for the much heavier and longer TSS-1R tether.

Reconciliation of Energy and Force Analysis:

By a force and torque balance analysis an optimum angle for the tether has been discovered at which it is possible to obtain a maximum in the drag component of the electrodynamic force. There is also an additional component of the electrodynamic force, the component in the vertical direction, $F_{EV=FE}\sin(\tau)$, which is downward for an upwardly deployed tether. This component of force combines with the gravity force of the Earth to effectively allow the host spacecraft to orbit a little faster than normal for that orbital altitude. It does not contribute to the deorbiting of the host spacecraft. But since this vertical component of force is created by current running through the tether, and that current is creating heat and dissipating energy as it passes through the tether, there might be some concern that the force and torque balance analysis above does not conform to the law of conservation of energy.

The inventors will now show, in a very general manner, that no matter what the tether angle, the electrical power being dissipated in the tether is exactly equal to the power being lost by the slowing of the host spacecraft.

The "deorbit power" P_D that must be removed from a spacecraft moving at a velocity v when that motion is opposed by a drag force F_{ED} is:

$$P_D=v\bullet F_{ED}=vF_E\cos\tau=vILB\cos\tau=I[vBL\cos\tau]$$

But, since the voltage V induced across the tether of length L and tilt angle τ moving at a velocity v through a horizontal magnetic field B is

$$V=E\bullet L=EL\cos\tau=vBL\cos\tau$$

Therefore:

$$P_D=IV=P_E$$

And the deorbit power P_D extracted from the slowing of the spacecraft by the drag component of the electrodynamic force is always exactly equal to the electrical power P_E being dissipated as heat in the tether circuits, independent of the tether angle.

Optimization of Tether Mass Distribution:

If it is not possible to use a piece of the host spacecraft as ballast mass, then the mass of the ballast must be included in the Terminator Tether™ mass. It would be desirable to minimize the total Terminator Tether™ mass, since every kilogram saved means that another kilogram's worth of revenue-producing transponders can be added to the working payload of the host spacecraft. Given a total mass for the Terminator Tether™ and the mass of the deployer/controller unit, it is possible to optimize the mass distribution between the ballast mass and the tether mass to obtain a minimum total Terminator Tether™ mass. A well-designed Terminator Tether™ will also have most, if not all, of the deployer mass incorporated into the ballast mass.

Assume that the total Terminator Tether™ mass consists of the deployer/controller mass m_D, the tether mass m_T, and the ballast mass m_B, with $m_B > m_T > m_D$. Of the three mass components in the Terminator Tether™, two of them affect the electrodynamic drag performance. If it is assumed that the ballast mass is a factor X larger than the tether mass, or $m_B = Xm_T$, the maxinum drag force that can be obtained is now:

$$F_{ED}(\max)=2.31 m_T (X+0.25)\Gamma L$$

If it is assumed that the control resistor has been adjusted so that this maximum value for the electrodynamic drag force is maintained as the motion of the spacecraft along its orbit moves the spacecraft into regions with different magnetic field strengths and plasma densities, then for the angle τ=35.26°, cos(35.26°)=0.817, and the maximum electrodynamic drag force in terms of the electrodynamic parameters will be:

$$0.817 vB^2L^2/(R_C+rdL^2/m_T)=F_{ED}(\max)=2.31 m_T (X+0.25)\Gamma L$$

or canceling out terms and rearranging:

$$(X+0.25)=0.353 vB^2L/\Gamma m_T(R_C+rdL^2/m_T)$$

It is now possible to make the further simplifying assumption that to maintain control of the tether, the control resistor needs to be roughly the same size as the tether resistance or $R_C \approx rdL^2/m_T$. Using this assumption produces an equation for the optimum value for the ratio X of the ballast mass to the tether mass:

$$\begin{aligned} X = vB^2/\Gamma rdL - 0.25 &= -0.25 + \frac{vB^2}{12\sin\gamma\cos\gamma\Gamma rdL} \\ &= -0.25\frac{\Lambda}{L} \end{aligned}$$

Where Λ is the "effective electrodynamic length".

If the tether is short, so that L is small, this equation indicates that the ballast mass must be increased to increase the gradient force, since it is the gradient force which determines the upper limit to the amount of electrodynamic drag force that can be generated without losing control of the tether.

Assuming the usual values for the Earth's magnetic and gradient fields, the velocity of the host spacecraft through the magnetic field, and the resistivity and density of aluminum, this equation becomes:

$$X=10.9/L-0.25$$

where L is in kilometers.

For a typical tether of length L=5 km, X=1.93. If the total mass for the Terminator Tether™ is 20 kg, or 2% of the host spacecraft mass, and the mass of the deployer is 10 kg, then the remaining 10 kg should be distributed so that 6.59 kg is in the ballast mass while 3.41 kg is in tether mass.

Optimization of Tether Length:

If the ballast mass consists of a piece of the host spacecraft, then the mass of the ballast does not have to be considered in the optimization of the Tether system. In this case, the optimum distribution of the Tether mass is to put as much mass as possible into the tether, with a minimum in the deployer/controller package. Under this assumption, the optimum length of the tether is determined by the desire to keep the Area-Time Product of the host spacecraft plus Tether to a minimum.

In a long tether of length L, the effective "collision" cross-sectional area is not the area of the tether, but the larger area produced by multiplying the length of the tether by sum of the width of the tether plus the width of the "target" spacecraft that would be damaged by the tether hitting it. Thus, to decrease the "area" portion of the Area-Time Product, it would be desirable to shorten the tether, making it thicker, and perhaps slightly wider, at the same time, thus keeping the same tether mass and electron collection area, and thereby maintaining the drag force and keeping the decay time at the same level. The result will be a shortening of the Area-Time Product.

If the tether is shortened too much, however, the smaller voltage generated across the shorter tether will leave less voltage margin for the operation of the plasma contactors and the battery recharge system. Since the maximum voltage that can be generated is about 200 V/km, and typical plasma contactors and battery, chargers take 25–100 V to operate, a minimum length for a Tether would be roughly 2 km. Host spacecraft operating in polar orbits, where the conditions for voltage generation are not as good, may require a tether length of 5 km or more.

Since many watts of heat power will be dissipated in the control resistor, means must usually be provided to radiate the heat away into space. One low-mass method of accomplishing this is to make the control resistor (or resistors) in the form of a long, electrically insulated, high resistivity wire similar to those used in electric blankets, but designed to operate at a higher temperature, and during the fabrication of the electrodynamic tether, incorporate the high resistivity wire (or wires) into the end of the tether closest to the control circuit by weaving or braiding the insulated high resistivity wire in with the uninsulated aluminum wire of the electrodynamic tether. The surface area of a long wire is very large, so in this extended wire configuration, exposed to the space all around it, the hot control resistor wire can self-radiate its power into cold space without incurring the mass penalty of a separate radiating surface.

Implementation:

The basic optimum structure for a Terminator Tether™ would be one of the many types of Hoytethers. A multiline (6–12 primary line) Hoytape™ will provide the largest contact area with the plasma, since both sides of the tape would be able to pass current to the plasma. If the spacing between the primary lines is chosen to be larger than twice the Debye length of the plasma, then the effective current collection area per unit length of the Hoytape is proportional to the width of the Hoytape mesh, not the diameter of the wires in the mesh. Thus, a Hoytape not only provides an assured longer life for the Terminator Tether™, but very short lengths will also provide a very large current collection areas.

The deployer for the tether can deploy the Terminator Tether™ either down or up or both. The deployer can stay attached to the spacecraft as was done in the SEDS missions, or perhaps a better alternative would have the deployer ejected from the spacecraft, with one end of the tether still attached to the spacecraft, reeling out tether as it leaves. The empty deployer would then act as a ballast mass at the end of the Terminator Tether™, which would improve the performance.

The "Remora Remover"

In addition to attaching Terminator Tethers to spacecraft before launch, it is possible to consider a missile-like application. This "Remora Remover" missile would use a Terminator Tether™ carried by a seeker missile similar to the small "hit-to-kill" missiles developed by the Space Defense Initiative Office that deployed a net loaded with oriented metal rods. The Remora Remover missile would hunt down a spacecraft that needs to be removed from space, but instead of hitting the spacecraft, the missile would be programmed to rendezvous with the spacecraft and attach itself to the host spacecraft using a hooked net, harpoon, or adhesive "sucker". The Remora Remover missile would then deploy the Terminator Tether™, which would bring down both the spacecraft and the missile.

The inventors have presented two analyses, backed up with data obtained from space flight experiments. One analysis was based on generalized energy conservation laws while the other analysis use force and torque balance arguments. Both analyses show that optimized aluminum wire tethers 2 to 5 km in length and massing just 1% to 5% of the mass of the host spacecraft can deorbit the host spacecraft in the order of a few weeks, thus mitigating the long-lived orbital debris hazard created by a constellation spacecraft after their end-of-life.

Power Augmented Operation of the Tether:

It is well known in the aerospace literature that if a spacecraft has a power supply and a conducting tether hanging from it, and the spacecraft is in an orbit or trajectory that takes it near a body, such as the Earth or Jupiter, which has both a magnetic field and a region of moderate density electron-ion plasma, and electrical current is pumped from the power supply through the tether and back through the plasma, that the current flowing through the tether will interact with the magnetic field of the body, producing forces on the tether and thence on the spacecraft, changing its orbit or trajectory. These forces can be used to increase or decrease the spacecraft altitude and/or inclination. The amount of altitude or inclination change is proportional to the ratio of the power available from the power supply divided by the mass of the spacecraft and varies with altitude. The unpowered Terminator Tether™ is a simple example of such a system, in which only altitude decrease is possible, although small amounts of both inclination increase or decrease are possible at the same time. Some typical references to this prior art are: Les Johnson, "Propulsive Small Expendable Deployer System Mission (ProSEDS)", Proceedings of the OAST 8th Advanced Propulsion Workshop, JPL, Pasadena, Calif., 20–22 May 1997; and Les Johnson, Joe Carroll, Robert D. Estes, Enrico Lorenzini, Brian Gilchrist, Manuel Martinez-Sanchez, Juan Sanmartin, and Irwin Vas, "Electrodynamic Tethers for Reboost of the International Space Station and Spacecraft Propulsion, AIAA Paper 1996.

Since the Terminator Tether™ of the invention is normally associated with a satellite that has a power supply in the form of a solar panel combined with a storage battery, the Terminator Tether™ can be operated in the "powered propulsion" mode if desired. Such a mode would be useful when attempting to avoid a collision between the Terminator Tether™ and another spacecraft. In such cases, the power from the solar panel, augmented by the power stored in the battery, can be used to temporarily operate the Terminator Tether™ in the propulsion mode instead of the normal drag mode. This would enable to Terminator Tether™ to raise its altitude and/or increase or decrease its inclination to avoid a collision.

In addition, the Terminator Tether™ could be operated in the "power-augmented drag" mode. In this mode, there will be a current induced in the tether by the motion of the spacecraft through the magnetic field, which will cause a drag force on the spacecraft. This induced current would then be augmented by additional current in the same direction generated by the solar panel and the storage batteries in the power supply. The increased current will cause an increased drag force. If there is a significant vertical component of the magnetic field there will also be an increased force normal to the orbital plane, which will cause an increased rate of change of inclination.

When the Terminator Tether™ is operated in the "powered propulsion" or "power-augmented drag" mode, the conditions for stable optimum operation will be essentially the same as in the "unpowered drag" mode. The reason the conditions stay the same is that the maximum tether force than can be effectively utilized is limited by the strength of the gradient force, which has not changed, since the length and mass of the tether and the ballast mass has not changed for these different modes of operation. As a result the optimum operational angle for the tether is still 35.26 degrees, and the optimum ratio of ballast mass to tether mass for different tether lengths and tether material is still determined by the analysis of the invention as is set forth above.

In the analysis given above, where the optimum tether angle was found, the tether was assumed to be in the plane of the orbit and lagging behind the spacecraft motion, since in the "unpowered drag" mode, that would be its normal position, although if the component of the magnetic field along the orbit were high, there would be some tilt of the tether out of the plane of the orbit, producing a force tending to change the inclination of the orbit. In either of the "powered" modes of operation of the Terminator Tether™, however, the tilt of the tether could be forward toward the motion of the spacecraft or strongly tilted to one side or the other of the orbital plane. In all these cases, if the electrodynamic force is allowed to become too large, and the tether angle exceeds 45 degrees, the restoring force of the gradient field will drop off and the tether angle will go unstable. As a result, the optimum angle for the tether that will give the maximum stable force, whether it is a maximum drag force, and maximum propulsion force, or a maximum inclination change force, will be 35.26 degrees, and the optimum ratio for the mass of the tether versus the mass of the ballast will be the same as for the unpowered drag case.

The analysis that gave the optimum angle as 35.26 degrees assumed that the tether would be oriented like a rigid rotor. In reality, variations in forces along the tether will probably cause the tether to hang in a slightly curved shape, where the optimum angle may not be exactly 35.26 degrees from the local vertical. The optimum angle of the tether as it leaves the host spacecraft in such a case is where the drag force is largest.

The present invention is discussed in this disclosure in terms of its space applications as a Terminator Tether™ useful for the removal of unwanted satellites. It should be understood, however, that the present invention is useful in any application where a space object can use a conductive tether to produce electrodynamic force through interaction with a magnetic field. The invention, therefore, should be limited not by this description, but only by the appended claims and their equivalents.

What is claimed is:

1. A method of operating a conductive tether attached to a space object, said conductive tether being oriented at an angle to magnetic field lines of an external magnetic field and said conductive tether moving across the magnetic field lines of said external magnetic field at said angle to producing an electric current in said conducting tether and a resulting electrodynamic force acting on said tether and said attached space object comprising,

Controlling the amount of electric current flowing in said conducting tether to vary the angle between the conductive tether the field lines of the external magnetic field and the electrodynamic force acting on said tether and attached space object.

2. A method as in claim **1** wherein said angle is less than 45 degrees.

3. A method as in claim **1** wherein said angle is 35.26 degrees.

4. A method as in claim **1** wherein said angle is controlled to average 35.26 degrees over time.

5. A method as in claim **1** wherein said angle is controlled to average 35.26 degrees over the length of the tether.

6. A method as in claim **1** wherein the space object and the tether connected to it are rotated about their center of mass while the conductive tether interacts with the external magnetic field.

7. A method as in claim **1** wherein the angle of the conductive tether to the external magnetic field is controlled by sensing a measurable parameter of the space object/conductive tether system.

8. A method as in claim **7** wherein the parameter is current flow in the conductive tether.

9. A method as in claim **7** wherein the parameter is the electrical power dissipated in the conductive tether and the current control system.

10. A method as in claim **7** wherein the parameter is the relative position of the space object and the position of the far end tip of the tether.

11. A method as in claim **7** wherein the parameter is the acceleration of the space object.

12. A method as in claim **6** wherein the parameter is the state vector of the space object as measured by the Global Positioning System.

13. A method as in claim **1** including the step of applying electric power to the conductive tether to change the state vector of the space object.

14. A method of operating a conductive tether attached to a space object, said conductive tether being oriented at an angle to the local vertical between said space object and a celestial body having a magnetic field having magnetic field lines external to said conductive tether; said conductive tether moving across said magnetic field lines of said external magnetic field at an angle to the local vertical to produce an electric current in said conducting tether and a resulting electrodynamic force acting on said tether and said attached space object comprising,

Controlling the amount of electric current flowing in said conducting tether to vary the angle between the conductive tether the local vertical between said space object and said celestial body to vary the electrodynamic force acting on said tether and attached space object.

15. A method as in claim **14** wherein said angle is less than 45 degrees.

16. A method as in claim **14** wherein said angle is controlled to average 35.26 degrees over time.

17. A method as in claim **14** wherein the space object and the tether connected to it are rotated about their center of mass while the conductive tether interacts with the external magnetic field.

18. A method as in claim **14** wherein the angle of the conductive tether to the external magnetic field is controlled by sensing a measurable parameter of the space object/conductive tether system.

19. A method as in claim **18** wherein the parameter is current flow in the conductive tether.

20. A method as in claim **18** wherein the parameter is the acceleration of the space object caused by the electrodynamic force acting on the space object.

21. A method as in claim **18** wherein the parameter is the change in the state vector of the space object as measured by the Global Positioning System.

22. A method as in claim **14** including the step of applying electric power to the conductive tether to change the state vector of the space object.

23. A method as in claim **14** wherein the celestial body is the Earth and the magnetic field is the Earth's magnetic field.

24. A method as in claim **14** wherein the celestial body is the sun and the magnetic field is the Sun's magnetic field.

25. A method as in claim **14** wherein the magnetic field is the vector sum of the magnetic fields from all celestial bodies in the solar system.

26. A method as in claim **14** wherein the conductive tether is a Hoytether.

(57) ABSTRACT

A new method is described to produce directional currents in the space lattice, the fundamental fabric of the universe. The currents may be unidirectional or vortexual in nature and are suitable for propulsion or the generation of electric power. For propulsion, the unidirectional currents are induced by charging capacitors possessing suitable geometries. This will allow the manufacture of vehicles capable of levitation and flight. The vortexual space lattice currents are produced in a suitable pyramid when electrostatic and magnetic fields interact transversally. The vortex causes charge separation and current in the coil wrapped around the pyramid.

METHOD AND APPARATUS FOR CONVERTING ELECTROSTATIC POTENTIAL ENERGY

CROSS-REFERENCES

[**0001**] This application claims priority from Provisional Application Ser. No. 60/169,378, by Peter Grandics, filed Dec. 7, 1999, also entitled "Method and Apparatus for Converting Electrostatic Potential Energy," the contents of which are hereby incorporated by this reference.

BACKGROUND OF THE INVENTION

[**0002**] This invention is directed to methods and apparatus for conversion of electrostatic energy. Specifically, this invention describes methods to cause directional movements in the space lattice.

[**0003**] To fully comprehend the theoretical basis for these methods, first the genesis of the elemental particles electron and positron needs to be discussed based on geometric or space relationships, and their interactions at the sub-elemental particle level must be clarified. The advantage of such an approach is that it can be visualized, and not just expressed mathematically. by definition, the word "structure" implies a geometric relationship, and such relationship must be of great importance in atomic structures even though they are hidden from direct view.

[**0004**] The study of geometric relationships of macroscopic structures of matter may provide important insights into the properties of matter at the microscale. Astrophysics suggests the universe probably started with an energy burst from one point. This big bang theory is supported by visual and electronic evidence that the galaxies are expanding away from a single center.

[**0005**] In stellar formation, gravitational pull and velocity generate a rotary vortex. Even in the relative absence of such factors, all objects spiral at some given rate peculiar to their special influences. A spiral is created when an object moves forward while rotating. Earth's movement in space is an example of this process. The Earth orbits the sun, while the sun pulls it along towards the direction of Vega in the constellation Hercules. the combined circular and forward motion creates a spiral. Our sun has the same motion in relation to the galaxy center. Our galaxy, the Milky Way, also spirals away from the Big Bang center.

[**0006**] Water going down a drain demonstrates some of the special influences affecting spiral formation. The spiral, caused by Coriolis forces, changes dynamically under the effects of gravitational pull, drain diameter, obstructions, temperature, pressure, volume, viscosity, and stirring. The spiral changes shape and acceleration but maintains the universal shape of a spiral. The water flow is responsive to all possible factors, and so is the spiral.

[**0007**] Remarkably, the spiral vortex has a "memory" of itself. When a vortex is distorted to become elliptical, it spontaneously returns to its original circular form. The vortex is a self-sustaining type of motion; its resiliency is comparable to that of atomic bodies.

[**0008**] Spirals condense energy and sine waves transmit it along a frictional line of force between them (**FIG. 1**). Spirals and waves could be considered illusions of each other. Two opposed spirals form a wave, or a wave produces two spirals. A sine is the producer of waves of spiral forces. Any fluid capable of supporting wave motion can also support vortex motion.

[**0009**] The spiral is the prominent form of organization of matter. The large proportion of spiral galaxies among celestial bodies visibly demonstrates this. On the microscale, even the building block of life, the DNA uses this structure and spirals are likely to be dominant at the level of the atom and below. This is the subject of the present theory. I propose that all atoms, all stellar formations use the mutable spiral to adapt to their spiral environment.

[**0010**] Another proposition is that all mediums of matter can be considered a type of crystal. Crystallinity is readily recognizable in the mineral world, but it is also a more general state of matter. Besides solid crystals, liquid crystals also exist. by definition, a crystal is a regularly repeating atomic arrangement, such as a chemical element, a compound or an isomorphous mixture. Therefore, the term crystal applies to material expressions where crystallinity is not so obvious, e.g., gases, complex biologics and various life forms, including viruses, bacteria and higher organisms. Air and water could be considered loose crystals subject to fast molecular drift. At low temperatures where molecular drift is reduced, gases form solid or liquid crystals. Soil and stone and metal are opaque cryptocrystals with slower rates of molecular drift. On the macroscale, the Earth could be seen as faceted crystal with its mountain ridges are the ridges of a geodesic sphere. Biopolymers such as DNA, proteins or polysaccharides fit well the definition of a crystal and are commonly made into crystals. All life can be seen as a crystal. From fish to humans, we are liquid crystals on a skeletal lattice.

[**0011**] Crystals are the shape of discrete units of matter and notably the channelized direction of energy, that is, the direction energy that flows unforced. Crystals form the basis for corpuscle-wave conversion. Crystals create resonance and conduct the flow of energy between states. Crystals can also be considered lenses. By definition, a lens is a device capable of refracting, or bending light. Light is an energy flow, so on a more general term, a lens can be defined as any object capable of changing the direction of energy flow. By this broader definition, even an electric wire is a lens as it is capable of changing the direction of flow of electrical energy. lenses communicate energy as part of the principle that all matter vibrate, all matter transmit, and all matter receives energy. The universe changes energy states with lenses. Following this line of reasoning, the universe could be viewed as a resonant crystal lens.

[**0012**] This observation is important because the universe is considered to be largely empty, the largest component of which is the so-called vacuum space. Since Nature seems to use the same geometrical organizing principles from macro to micro, I suggest that the vacuum space must also be "crystalline". Since the term crystalline is associated with material of which the vacuum space is substantially devoid, I will use an extended meaning of "structured" when discussing crystallinity of vacuum space.

[**0013**] The theory of "crystalline" vacuum space was introduced by Simhony (Simhony, M. (1990) The Electron-Positron Lattice Space, Cause of Relativity and Quantum Effects, Physics Section 5, The Hebrew University, Jerusalem., and Simhony, M. (1994) Invitation to the Natural

Physics of Matter, Space, and Radiation, World Scientific Publishing Co., London, UK.). Simhony reasoned that three-dimensional physical phenomena must have three-dimensional physical causes and explanations.

[**0014**] He demonstrated that physical reality can be described by the laws of classical physics supplemented by the presence of a space lattice. This led to the development of the theory of an electron-positron lattice space (epola for short). In the epola, bound electron-positron pairs reside at the lattice sites of a face-centered cubical “crystal” structure similar to that of NaCl crystals (Kennon, N. F. (1978) Patterns in Crystals, John Wiley & Sons, New York.).

[**0015**] The epola theory allowed a physical explanation of all yet unexplained postulates of quantum mechanics and relativity including the particle-wave duality, the quantized nature of electron orbits in the atom, the electromagnetic radiation, the photon, and gravitational interactions as well as the relationship of electrostatic, magnetic and gravitational interactions. He demonstrated gravity to be a derivative of electromagnetism.

[**0016**] There is a large body of evidence suggesting that the vacuum space is not empty at all. Experiments verify that the vacuum space contains an enormous residual background energy (some examples are: Boyer, T. H. (1985) The classical vacuum (zero-point energy) Scientific American 70-78, Haisch, B., Rueda, A. and Puthoff, H. E. (1994) Beyond $E=mc^2$, The Sciences, 34, No. 6, 26-31, and B.

[**0017**] Haisch and A. Rueda, (1999).On the relation between zero-point-field-induced inertial mass and the Einstein-de Broglie formula, Physics Letters A, in press), called zero-point energy (ZPE). The ZPE manifests as a pervasive and vast electromagnetic field called the zero-point field (ZPF). a dynamic field, ZPF is a virtual plasma, with particles arising and disappearing of a background energy field serving as a baseline, or zero point, for all physical processes. The ZPE remains even at absolute zero. Simhony has described zero-point energy fluctuations as analogous to brownian motion of epola particles around their lattice sites. A potential alternative term for the lattice space is zero-point-field (ZPF) described in 1994 by Haisch, Rueda and Puthoff (Haisch, B., Rueda, A. and Puthoff, H. E. (1994) Beyond E=mc2, The Sciences, 34, No. 6, 26-31). This area remains an active field of research.

[**0018**] Simhony also suggested that all particles of matter are directly formed from the lattice space, the mechanism of which remains undetermined. The present theory intends to answer this question in terms of lattice space.

[**0019**] I propose that the vacuum space has a lattice structure similar to that introduced by Simhony. this structure is a face-centered cube having 27 lattice sites (**FIG. 2**). on the lattice sites reside the elemental “particles” forming all particles of matter. These are “particles of energy” rather than particles of matter.

[**0020**] I propose that the “particle of energy” of the space lattice, called here the subtle electron, is a spiral energy vortex tied into itself in the form of a circumvolution cissoid. The circumvolution cissoid is a spiral turn around an axis converging into an apex, in a self-imploding, self-sustaining vortex motion (**FIG. 3**). The vortex pulsates and its vibration is a function of **(2_Ø)x, where Ø is the Fibonacci series number and x**=0,1,2,3, the number of turns the circumvolution cissoid makes. Once started up, such a vortex would run practically indefinitely inside the space lattice.

[**0021**] The internal friction of such a space lattice must be so low that it would only be noticeable as a red shift in the spectra of distant galaxies. The space lattice, like its constituent energy vortices, must also be a resilient structure with only limited compressibility. At the same time, it must have fluidity since it is capable of transmitting waves with transverse displacement. In the absence of atomic oscillators, the space lattice would be incapable of dissipating energy in the form of heat.

[**0022**] Vortices maintain their circular forms as well as their proportions and dimensions. The adjacent vortices have a coordinating effect that establishes axial alignment and rolling contact between vortices within the space lattice. In that sense, there is a great deal of similarity between crystals of material bodies and the structure of the space lattice. I postulate that the space lattice is an incompressible, frictionless fluid made out of cubes of units cells of subtle electron vortices.

[**0023**] We can consider the space lattice equivalent to motion. A space lattice in motion necessarily has inertia. Although inertia is generally attributed to moving material bodies, it is actually a property of motion. Inertia is just the continuity of motion. In the case of vortex motion the inertia is localized. Localized inertia can also be called momentum. To account for the elemental particles of matter, we need a space lattice that is capable of moving.

[**0024**] Anderson discovered in 1932, that when 1.02 MeV photon energy is absorbed into the vacuum space, an electron-positron pair can appear. this observation is explained here as a glimpse into the formation of elemental particles of matter. To become matter, energy must become more angular. This hypothesis is derived from the observation that all material expression is a type of crystal, and is the compound and derivative of a fundamental triangular form which all the seven crystal systems can be derived (Kennon, N. F. (1978) Patterns in Crystals, John Wiley & Sons, New York.). The mechanics of this expression at the level of the space lattice are explained as follows: As the energy of electromagnetic radiation propagates through the space lattice, it polarizes the subtle electron energy vortices (for analogy see **FIG. 1**). Subsequently, the “energy particles” of the space lattice, the subtle electrons, undergo a phase transition similar to the condensation of gases. This happens at the resonant frequency of the 1.02 MeV gamma radiation.

[**0025**] The 27 subtle electrons of the unit cell of space lattice rearrange into a pyramidal segment of the cube (**FIG. 5**) on six levels each forming circles of vortices. An open-flat presentation of the rearrangement is shown in **FIG. 4**. This structure is the postulated smallest unit of matter. note that the cube is composed of six interlocking pyramids so the cube and the pyramid are resonant structures. Inside the pyramid, the subtle electron rings form a vortex capable of circulating the fluid space lattice. The pumping action is driven by the self-sustaining, pulsating vortex motion of its constituent subtle electrons (**FIG. 3**). The overall shape is a cone fitting inside the pyramid. The formation of matter follows the geometry of the space lattice (**FIG. 5**) and thus we may conclude that the space lattice provides the blueprint for matter.

[**0026**] An electron is produced when two such cones are joined in a tip-to-tip conformation (**FIG. 6**). The positron is made out of two vortices (cones) facing base-to-base. The energy vortices which make up the electrons have a resilient vibratory structure which should be capable of vibrating at various frequencies and modes. This would allow us to account for the series of spectral lines, a signature of absorbing and emitting energy at various frequencies.

[**0027**] These complex vortex particles have a pumping effect and circulate the fluid space lattice. For the electron, the space lattice is drawn in polarly and expelled equatorially. For the positron, the space lattice is drawn in equatorially and expelled polarly (**FIG. 7**). The direction of circulation of fluid space lattice determines the positive or negative polarities. When in close proximity, a specific flow coupling occurs between the electron and positron (**FIG. 7**). It is quite probable that a similar flow coupling exists between a proton and an electron inside the atom, although such coupling is stable in the case of the proton. This is likely a result of the different vibratory structure of the vortex proton.

[**0028**] The instability of the electron-positron pair is also derived from this model. The perfectly fitting, counter-rotating cones of energy extinguish each other with the release of a combined energy of 1.02 Mev. This results in the reconstitution of the respective unit cells of the space lattice along with the release of the phase transition energy.

[**0029**] The size of the subtle electron is estimated based on the “nuclear radius” of 0.1 fm for the electron, to be approximately 0.005 fm. The lattice constant for the unit cell of space lattice is approximately half of the “nuclear radius” of the electron, i.e,.0.05 fm. This indicates that the space lattice is quite dense compared to atomic bodies.

[**0030**] The model explains the attraction of free electric charges as follows (**FIG. 8**): Opposite charges move towards each other. This movement is due to the equatorial circulation of fluid space lattice from the negative charge to the positive charge and the polar circulation of space lattice from the positive to the negative charge. The attraction of the vortices pull the two partners together. The electrostatic field between separated charges is defined as the flow of the space lattice from the protons to the electrons and the outside return flow of space lattice from the electrons to the protons (see **FIG. 8**). This explanation will eventually lead to a hydromechanical theory of electricity.

[**0031**] Interestingly, there is a net unidirectional flow of fluid space lattice in the axial direction of the free electric charges (**FIG. 8**) flowing in at the negative pole and flowing out at the positive pole. if the charges have a steady parallel orientation, e.g., as in an electric condenser, then a pressure differential must arise in the space lattice around the opposite poles of the condenser. To fully appreciate the significance of this conclusion, we must first examine how material bodies accelerate through the space lattice.

[**0032**] Accelerating objects encounter resistance facing an increased pressure of the space lattice at the front end and a reduced pressure at the rear end of the object. This situation is common to all propulsion methods which apply mechanical force on the physical object. Therefore, it is logical to suggest that a pressure differential of space lattice at the opposite sides of material bodies is always accompanied by a change in the rest or motion of such bodies. To obtain a propulsion force, instead of exerting force on the physical object we should transfer the space lattice that controls the behavior of the object from the rear end of the object to its front end.

[**0033**] Therefore, a sufficiently charged object in which the charges have a steady parallel orientation should behave as an accelerating object, i.e., it should move toward the direction of its positive pole. In fact, this happens due to its own generated space lattice pressure differential Now that the fundamentals are developed, the effect may provide the basis for a new propulsion and gravity cancellation method, and may give us insights into the mechanism of gravitation. A craft utilizing such propulsion method could exhibit inertialess acceleration as it would meet no resistance from the surrounding space lattice.

[**0034**] The theory also allows us to develop strategies for tapping into the energy of the space surrounding us. Separated charges in an electric condenser cause a directional flow of the fluid space lattice. Conversely, if we could induce a directional flow of the space lattice, it would cause a separation of charges in material objects. To explain how such an effect could be produced, first the physical basis of magnetism must be explained.

[**0035**] I have described the physical basis for the electrostatic field as a flow of a space lattice current from the positive charges to the negative charges and back on the outside to the positive charges. I shall now explain how these space lattice currents flow in an electric wire. The space lattice flow which connects the electrons to the protons of the atoms in the wire becomes extended in the length of the wire. This is the same direction as the direction of movement of electrons which, in the current, flow in the outer shell of the wire. The external return flow of the space lattice will be in the opposite direction in the space around the wire. This flow constitutes the magnetic field. In a solenoid, the surrounding space lattice flows in the opposite direction relative to the path of the electrons. The magnetic effect will appear as either N or S magnetic poles. The magnetic poles are mirror images of each other. This suggests that a single isolated magnetic pole cannot exist.

[**0036**] In the electrostatic field, the outside space lattice currents flow between electrically charged particles. The magnetic field, on the other hand exhibits a closed circuit flow of the space lattice along the path of a solenoid or a circuit. Electric and magnetic forces are produced by movement of the space lattice in spirals or whirls.

[**0037**] An electric charge and a magnetic pole do interact even though they do not apply any force to each other. A magnetic pole will bring about a directional orientation of the electrons in a charged object, while an electric charge will cause the electric polarization of the adjacent surface of a magnetic pole.

[**0038**] The final question remains is the superimposition of electrostatic and magnetic fields on each other. The practical significance of the interaction of axially oriented electrostatic and magnetic fields is likely to be small compared to their interaction at an angle. A transversal superimposition of a magnetic field on an electrostatic field will cause the distortion of both fields. The axial flow of the space lattice between the electric poles, which is the physical basis for the electrostatic field, will be distorted, but its circulation will continue. Similarly, the rotating space lattice, which is the basis for the magnetic field, will also be distorted, flowing in irregular circuits.

[**0039**] To study the transverse superimposition of electrostatic and magnetic fields, a shaped electrostatic field must be created (**FIG. 9**). When a magnetic field interacts with the shaped flow of the space lattice, it could result in the formation of a space lattice vortex at the points where the two flows intersect. This is based on previous hypothesis that the space lattice is an incompressible fluid, wherein the intersecting currents cannot penetrate but distort each other's flow patterns.

[**0040**] To expand this shaped electrostatic field into three dimensions, a pyramid is required. I have already discussed the importance of the pyramidal geometry in the formation of matter. The pyramidal geometry may also be important for producing a space lattice perturbation, which is the equivalent of a magnetic field when it follows a rotational symmetry (e.g. a vortex).

[**0041**] If with transversally superimposed electrostatic and magnetic fields a pyramid did indeed produce a vortex in the space lattice, then the rotational flow of the space lattice should cause the separation of charges and an electric current in material bodies, as predicted by this theory. This means that under appropriate conditions, a pyramid could become a power generator.

[**0042**] For power generation in a pyramid, the source of the electrostatic and magnetic fields could potentially be the Earth. The earth has a high voltage electric field such that the earth's surface is negatively charged while the atmosphere is positively charged (Feynman, R. P. (1964) Lectures on Physics, v.2, 9-2, Addison Wesley, Inc., Palo Alto, Calif.). The voltage field is believed to be maintained by the Sun's radiation energy and/or cosmic ray energy and extends from the ionosphere to the surface creating a potential difference of about 400,000 V. The Earth's electrostatic field never seems to get depleted despite all the storm activities and discharging of energy. The voltage gradient is estimated to be 200 V/m around the surface of the earth. The total energy reaching earth at any moment is about 700 MW (400,000 V multiplied by a current of 1800 A). The magnetic field strength of the earth is about 0.5 Gauss and exhibits continuous pulsations with main frequencies of 8 to 16 Hz.

[**0043**] Therefore, the earth's electrostatic and magnetic fields could potentially be utilized to create a space lattice vortex in and around a sufficiently sized pyramid. This hypothesis has been tested experimentally. The earth's electrostatic field was modeled as described in the Examples.

[**0044**] Therefore, there is a need for an improved method and apparatus for the conversion of electrostatic energy as described herein.

SUMMARY OF THE INVENTION

[**0045**] Pursuant to this invention new techniques are described to produce directional currents in the space lattice. The currents are induced either by separated charges, properly positioned magnetic fields or by the interaction of electrostatic and magnetic fields at an angle, specified by the side angle of a pyramid. The induced space lattice currents can be utilized to generate specific effects which may vary from propulsion, to gravity cancellation and power generation.

[**0046**] In particular, an aspect of the present invention is a method producing directional currents in the space lattice utilizing:

[**0047**] (1) separated electric charges; and

[**0048**] (2) the interaction of electrostatic and magnetic fields.

[**0049**] In one preferred embodiment of the invention, electric charges are separated in an oriented fashion. The orientation can be a parallel orientation. The orientation can be obtained in a capacitor. The capacitor can be used for the propulsion of a vehicle. The capacitor can provide lift and lateral movement control for said vehicle.

[**0050**] The interaction of electrostatic and magnetic fields can be set up in a pyramid.

[**0051**] The interaction can produce a vortex in the space lattice.

[**0052**] The vortex can be tapped to produce electric power, which can be obtained by wrapping a coil around the pyramid.

BRIEF DESCRIPTION OF THE DRAWINGS

[**0053**] The following invention will become better understood with reference to the specification, appended claims, and accompanying drawings, where:

[**0054**] **FIG. 1** is a diagram showing the relationship between a spiral and a wave;

[**0055**] **FIG. 2** is a diagram demonstrating the geometry of the space lattice;

[**0056**] **FIG. 3** is a diagram demonstrating the circumvolution cissoid;

DESCRIPTION OF THE PREFERRED EMBODIMENT

[**0065**] Pursuant to this invention, novel methods are described to induce directional currents in the space lattice which is postulated to be part of the boundary conditions of the Universe. These methods are useful in providing for the conversion of electrostatic energy into a useful form. The first method relates to generating an unidirectional flow of the space lattice which could be useful in cancelling gravity and generating a propulsion force. A possible configuration for keeping the charges separated and stored is in the form of a capacitor. The shape of the capacitor and the body of such device is important for optimal performance. A pyramidal or conical shape is preferred for the alignment of the capacitors (**FIG. 10**). Optimally, the shape of the capacitor follows the shape of the craft.

[**0066**] In **FIG. 10**, the pyramid **100** is surrounded by a detector coil **102** which is in turn connected to an oscilloscope **104**. In the experimental setup shown, the field is established by a top plate **106** and a ground **108** connected to a source of DC electrical energy **110**.

[**0067**] The conductive elements of the capacitor are layered into the pyramidal or conical segment of the hull of such craft. Optimally, there should be several layers of negatively charged conductors on the outside while a single layer of positively charged conductor in the inside of the craft. All conductive elements should be carefully insulated in order to keep the charges inside the capacitor.

[**0068**] In the center of the craft, a conductive, insulated pole is mounted such that the pole extends out into the exterior at the top of the craft. The tip of that pole has a metal ball mounted on which is also positively charged. When all the capacitor plates are charged, they induce an unidirectional, upward flow of the space lattice. This means that the space lattice pressure above the craft will be higher than the space lattice pressure at the bottom of the craft. This pressure differential is unstable and progresses towards an equilibrium. It will grab the craft and propels it forward in order to eliminate the pressure gradient. This requires that a sufficiently high voltage be applied. My estimation is that about 5 kV is needed to lift every gram of an object. The capacitors incorporated into the hull will give control over lift.

[**0069**] To obtain directional control over all three axes of movement, three capacitors need to be mounted at the bottom of the craft apart from each other. These capacitors, could take the shape of a ball and would be mounted on retractable shafts. The top half of the capacitors would be positively charged while the bottom half is negatively charged. When in flight, the capacitors are retracted and charged based on the needs of directional control. To achieve forward movement, the charges on one capacitor facing the direction of the desired path should be reduced relative to the other two capacitors. This would make the craft tilt forward and start moving in that direction. An alternative method of lateral directional control could be obtained by dividing the capacitor bank in the hull into segments which segments could be charged individually.

[**0070**] Upon landing, the three ball capacitors would be protracted on their shafts and serve as landing gear. On landing, they would be discharged because the earth is the greater ground. On launching, the main capacitors of the body would be activated causing a lift-off. The three capacitor landing gear would then be retracted and charged up so that they can function for lateral directional control. Onboard static generators would supply the voltage required for the operation of the craft.

[**0071**] The most significant aspect of this type of propulsion system would be the loss of inertia during acceleration. Inertial forces pose great obstacles to improving the performance of current propulsion techniques. Since we are now in control of the space lattice surrounding the craft, it will encounter no resistance from the space lattice. The passengers of such craft would feel no forces acting upon their bodies even if the craft achieved enormous accelerations.

[**0072**] This overall design is suitable for the development of a wide range of transportation vehicles, from automobile-type to aircraft and spacecraft. The impact of such a technology on our economy would be enormous. We could eliminate a major factor in environmental pollution, the generation of greenhouse gases which place a great stress on our ecosystem. In the United states, 66% of the greenhouse gases are produced by transportation vehicles and just 34% by power generation. The signs of global warming and the deterioration of the ecosystem are visible from every direction.

[**0073**] The developing countries are bent on establishing the same economical model evolved in the developed countries, representing about 16% of the world population. Worldwide mass deployment of our current energy technologies would most likely cause an environmental catastrophe which may terminate higher life-forms on this planet.

[**0074**] This makes it very important that the focus of our energy sector shifts towards renewable, non-polluting sources of energy. The subject invention offers a solution in this regard. The transversal interaction of electrostatic and magnetic fields in and around a pyramid offers the potential to tap into the electromagnetic field of our planet. I have found that a pyramid becomes a power generator when the electrostatic voltage field gradient of the earth is reproduced around it. Tapping the energy field was as simple as placing a coil around the pyramid.

[**0075**] The optimal size production pyramid is likely going to be large. The optimal material composition may be alternative layers of metal and dielectric to maximize the total amount of charges the pyramid can hold. This is important for increasing the performance of the pyramid. A coil is then wrapped around the pyramid to tap into the generated field. The orientation of the pyramid to the magnetic North pole does not seem to be a prerequisite for operation. Such a pyramid generator will be called the pyramitron.

[**0076**] The following Examples illustrate the features and advantages of the subject invention. Accordingly, it is to be understood that the description in this disclosure is to facilitate comprehension of the invention and should not be construed to limit the scope thereof as persons skilled in the art can, in light of this disclosure, generate additional embodiments without exceeding the scope or departing from the spirit of the claimed invention.

EXAMPLE 1

[**0077**] Demonstration of the pyramitron: For the experiments, I have randomly selected a one-foot base length foam pyramid from a pyramid vendor (The Pyramid Project, Ft. Wayne, Ind.). The outside of the pyramid was covered with aluminum foil. The pyramid was placed on a 2'x2' insulating polyethylene platform equipped with an adjustable height 2'x2' size aluminum top plate, 1/16" thick (**FIG. 10**). The height of the aluminum plate was adjusted as needed and a gap of 1 ¼" between the plate and the tip of the pyramid was used in the experiments.

[**0078**] A high voltage (HV) CRT power source producing 30 kV DC was taken from a television set. I have assumed that an actual energy producing pyramid should be relatively high in order to obtain a large voltage drop from its tip to the ground. Therefore, assuming a height of 150 m for a life-size pyramid and a voltage drop of 200 V/m near the surface of the Earth, the 30 kV voltage is in the range of the voltage-drop expected for the height of a practical size pyramid.

[**0079**] The positive pole was attached to the top aluminum plate. This simulated the positive charge of the atmosphere. One corner of the pyramid was attached to the negative pole of the high voltage power source, while the opposite corner of the pyramid was grounded. This setup served as a model for the electrostatic field distribution around a potential life sized pyramid.

[**0080**] As controls, either a 1'x1' sheet of aluminum foil or an aluminum foil-covered box, having the main dimensions of the test pyramid (1'x1'x⅝"), was used as a negative pole. The detector coils were made by winding up a 24 gauge enamel-coated magnetic wire (20 turns, approximately 8 cm diameter). A Tektronix high-frequency oscilloscope, model no.2236 was used for signal acquisition and analysis.

[**0081**] The first set of experiments were control measurements with the box of the same height and base lengths as the test pyramid. The detector coil was placed on the top of the box. Measurements were taken with and without the high voltage applied. One corner of the box was attached to the HV power source (negative pole) and the opposite corner to the ground. The same arrangement was used for the flat square (1'x1') foil. The peak-to-peak signal amplitude for the box was 8 mV and the signal frequency was 2 MHz. For the flat foil sheet, the signal amplitude was 12 mV with a frequency of 1.43 MHz. The signal form was of a decaying sine wave.

[**0082**] When high voltage was applied to these shapes, a signal amplitude of 14 mV was obtained for the flat sheet and a 16 mV for the box. The signal frequency was 1.54 MHz for the flat sheet and 2 MHz for the box. The wave forms were of decaying sine waves in all these experiments.

[**0083**] When the pyramid was tested without HV, the peak-to-peak signal amplitude was measured at 60 mV with a frequency of 2 MHz. The wave form was different from those of the control experiments; it was a modulated, decaying sine. When the high voltage was applied, the signal amplitude increased up to 180-200 mV, while the frequency remained at 2 MHz. The pyramid produced a signal intensity significantly higher than the controls. When a metal (aluminum) pyramid of the same size (wall thickness 1/16" inch) was tested in the same high voltage field using the same detection coil, a voltage of 1-1.5 V was detected at the frequency of 2 MHz.

[**0084**] The experiments confirmed theoretical assumptions about the pyramidal shape's ability to cause perturbations in the space lattice when the pyramid is placed in transverse electrostatic and magnetic fields. The resulting space lattice vortex causes a separation of charges in the detection coil, producing a voltage signal greatly exceeding control levels. Control values for the flat sheet and the box in the electrostatic field were at the level of the background noise. Thus, when the electrostatic and magnetic fields intersected at 90° or 0°, no effect was observed. However, when the fields intersected at an angle defined by the pyramidal shape, a large signal was produced. The pyramid is clearly instrumental in generating the signal. This finding provides the second experimental proof for the present theory of electric polarities. It also demonstrates that potentially, we may be able to tap into the electromagnetic field of our planet and draw electric energy. The practical implications of this finding are enormous.

I claim:

1. A method producing directional currents in the space lattice utilizing:

(a) separated electric charges; and

(b) the interaction of electrostatic and magnetic fields.

2. The method of claim 1 wherein said electric charges are separated in an oriented fashion.

3. The method of claim 2 wherein said orientation is a parallel orientation.

4. The method of claim 3 wherein said orientation is obtained in a capacitor.

5. The method of claim 4 wherein said capacitor is used for the propulsion of a vehicle.

6. The method of claim 5 wherein said capacitor is providing lift and lateral movement control for said vehicle.

7. The method of claim 1 wherein interaction of electrostatic and magnetic fields is set up in a pyramid.

8. The method of claim 1 wherein said interaction is producing a vortex in the space lattice.

9. The method of claim 8 wherein said vortex can be tapped to produce electric power.

10. The method of claim 9 wherein said electric power is obtained by wrapping a coil around the pyramid.

(57) **ABSTRACT**

Systems, methods and apparatus for harvesting atmospheric electricity are provided. The system includes a laser configured to form a plasma filament and a collector configured to collect electricity flowing along the plasma filament. The plasma filament comprises an electrically conducting plasma filament. Atmospheric electricity may be collected by having the plasma filament form at least a part of a conducting path: (1) between ground and a cloud, (2) between differently charged regions of the same cloud, (3) between differently charged regions of different clouds, and (4) between different regions of atmosphere, where there is a vertical voltage gradient. When the plasma filament is not long enough to form the entire conducting path, a lightning may be triggered to complete the conducting path needed to collect atmospheric electricity.

SYSTEM FOR HARVESTING ATMOSPHERIC ELECTRICITY

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT

Not applicable.

FIELD OF THE INVENTION

The subject technology relates in general to a system for harvesting atmospheric electricity, and more particularly to a system that uses a laser to form an electrically conducting plasma filament for harvesting atmospheric electricity.

BACKGROUND

It is well known that large quantities of electrical energy are present in the atmosphere and in lightning. Lightning was one of the first forms of electricity harnessed in the modern age by Benjamin Franklin in his famous kite experiment.

A lightning discharge typically contains on the order of 10^{10} Joules of energy. It has been estimated that the total electrical power of lightning across the Earth is of the order of 10^{12} watts. Collection of electrical energy from clouds associated with lightning is a problem that needs to be resolved.

Lightning is but a small part of the total electrical activity of the atmosphere. When a local build up of charge above the Earth exceeds the local breakdown potential of the atmosphere a lightning discharge occurs. However, there is a continual invisible flow of charge from Ionosphere to Earth occurring day and night over the entire surface of the globe, which exceeds the global lightning power output by many times. The source of this flow of charge from the atmosphere to Earth is the Sun. Radiation from the Sun helps form most of the ions found in the Ionosphere, a highly charged region above the atmosphere, through ionization of atmospheric molecules. Solar radiation, particularly in the UV and soft x-ray bands, consist of photons whose energies are well suited to ionization. The Sun also emits continuously a solar wind of positively charged particles. These are captured by the Earth's magnetic field and further contribute to the Ionosphere. The positively charged region in the Ionosphere in turn induces (by electrostatic induction) a negative charge on the surface of the Earth. The Earth becomes in effect an enormous spherical capacitor. A potential gradient or electric field is thus established between the two "plates" of this capacitor, the Ionosphere (or Electrosphere) and the surface of the Earth. While the upper strata of the atmosphere conduct electricity reasonably well, the lower levels act as an insulator or dielectric. Near the surface of the Earth, this electrostatic potential gradient is on the order of about 100 Vm^{-1} in summer, rising to 300 Vm^{-1} in winter. This flow of charge can be tapped and directed to provide useable electrical power. This source of atmospheric electricity has the following advantages: (1) Simple and robust technology; (2) Low cost technology—much cheaper than photovoltaics or wind turbines; (3) Available day and night in all weather conditions—in fact, more power is produced at night than during the day; and (4) Available at any point on the Earth's surface. Collection of this source of atmospheric electricity is another problem that needs to be resolved.

SUMMARY

According to various aspects of the subject technology, a system for harvesting atmospheric electricity is provided that solves some or all of the foregoing problems. In some aspects, the system may be used to harvest atmospheric electricity arising from an electrostatic potential gradient: (1) between ground and a cloud, (2) between differently charged regions of the same cloud, (3) between differently charged regions of different clouds, and (4) between different regions of atmosphere, where there is a vertical voltage gradient. In other aspects, the system may be used to harvest atmospheric electricity arising from an electrostatic potential gradient between the Ionosphere (or Electrosphere) and the surface of the Earth.

According to various aspects of the subject technology, a system for harvesting atmospheric electricity is provided. The system comprises a laser configured to form a plasma filament. The system also comprises a collector configured to collect electricity flowing along the plasma filament.

According to various aspects of the subject technology, a method for harvesting atmospheric electricity is provided. The method comprises forming a plasma filament with a laser. The method also comprises collecting electricity flowing along the plasma filament.

According to various aspects of the subject technology, an apparatus for harvesting atmospheric electricity is provided. The apparatus comprises means for forming a plasma filament with a laser. The system also comprises means for collecting electricity flowing along the plasma filament.

It is understood that other configurations of the subject technology will become readily apparent to those skilled in the art from the following detailed description, wherein various configurations of the subject technology are shown and described by way of illustration. As will be realized, the subject technology is capable of other and different configurations and its several details are capable of modification in various other respects, all without departing from the scope of the subject technology. Accordingly, the drawings and detailed description are to be regarded as illustrative in nature and not as restrictive.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are included to provide further understanding of the subject technology and are incorporated in and constitute a part of this specification, illustrate aspects of the subject technology and together with the description serve to explain the principles of the subject technology.

FIG. **1** illustrates a first example of a system for harvesting atmospheric electricity. The system comprises a laser configured to form a plasma filament and a collector configured to collect electricity flowing along the plasma filament. The plasma filament forms a conducting path between ground and a cloud.

FIG. **2** illustrates a second example of a system for harvesting atmospheric electricity. A plasma filament and a lightning together form a conducting path between ground and a cloud. A condensing mirror directs the beam of laser towards the cloud.

FIG. **3**A illustrates a third example of a system for harvesting atmospheric electricity. A laser system situated on an airplane forms two plasma filaments that together complete a conducting path between a first region of a cloud and a second region of the cloud. The first region of the cloud and the second region of the cloud carry opposite electric charges. A collector configured to collect electricity flowing along the two plasma filaments is also situated on the same airplane as the laser system.

FIG. **3**B illustrates a fourth example of a system for harvesting atmospheric electricity. It is similar to FIG. **3**A, except two lightnings complete the conducting path between a first region of a cloud and a second region of the cloud (i.e., a first lightning electrically connects the first region of the cloud to one of the plasma filaments and a second lightning electrically connects the second region of the cloud to the other plasma filament).

FIG. **4** illustrates a fifth example of a system for harvesting atmospheric electricity. A laser system situated on an airplane forms two plasma filaments that together complete a conducting path between a first cloud and a second cloud. The region of the first cloud that is connected to the first plasma filament and the region of the second cloud that is connected to the second plasma filament carry opposite electric charges.

FIG. **5** illustrates a sixth example of a system for harvesting atmospheric electricity. A laser situated on an airplane forms a plasma filament that completes a conducting path between a first region of atmosphere and a second region of atmosphere. A collector situated on the same airplane as the laser can collect electricity flowing along the plasma filament, because a vertical voltage gradient exists between the first region of atmosphere and the second region of atmosphere.

FIG. **6** illustrates an example of a collector configured to collect electricity flowing along the plasma filament. The collector may be a charge collection circuit characterized by capacitance, inductance, and resistance. The electricity may be collected by charging a capacitor.

DETAILED DESCRIPTION

The detailed description set forth below is intended as a description of various configurations of the subject technology and is not intended to represent the only configurations in which the subject technology may be practiced. The appended drawings are incorporated herein and constitute a part of the detailed description. The detailed description includes specific details for the purpose of providing a thorough understanding of the subject technology. However, it will be apparent to those skilled in the art that the subject technology may be practiced without these specific details. In some instances, well-known structures and components are shown in block diagram form in order to avoid obscuring the concepts of the subject technology. Like components are labeled with identical element numbers for ease of understanding.

FIG. **1** illustrates a first example of a system **100** for harvesting atmospheric electricity. The system **100** comprises a laser **110** configured to form a plasma filament **120** and a collector **130** configured to collect electricity flowing along the plasma filament **120**. The plasma filament **120** forms a conducting path between ground and a cloud **140**.

The plasma filament **120** comprises an electrically conducting plasma filament. The plasma comprises of electrons and positive ions. The electrically conducting plasma filament may be formed in atmosphere using an ultra short pulse laser (USPL). The USPL forms a plasma filament by raising the conductivity of a very small diameter channel (~100 microns or less) for a very brief time. The propagation of high power (~10^{14} W/cm^2) pulses from the USPL is accompanied by filamentation—self-channeling of femtosecond laser pulses in stable high-intensity light filaments with ~100 microns diameters (so that the Kerr effect focusing balances defocusing due to plasma formation). This filamentation keeps the beam virtually free of diffraction divergence. The long plasma strings have high electron densities (10^{16}/cm^3) which support high conductivities. The ionization of air at these intensities results from multi-photon processes. Filamentation has been produced and detected at altitudes as high as 13-20 km. Almost no beam scattering occurs in filamentation phenomenon, and virtually all the pulse energy is invested in ionization of air molecules. With the typical electron density and channel diameter, a 160 mJ pulse is sufficient to generate a 1 km long channel.

Once initiated, plasma filaments cannot go on forever, and typically only propagate a kilometer or so before energy depletion and exhaustion. However, by using two coaxial USPL projection optics having different time-lensing parameters, a near and far filament could be initiated in a "daisy-chain" to extend the total length of the conductive channel. The onset of filamentation in the far filament is time-lensed to coincide with the exhaustion range of the near filament. Additionally, using negative chirp, femtosecond laser pulses can propagate almost without loss until different frequency components of the wave packet, propagating at different speeds due to dispersion in air, come together at a certain desired location so that the laser intensity there exceeds the filamentation threshold, resulting in long ionized filaments created at a distance of up to several miles from the laser source. In other words, negative chirp is used to essentially focus a beam of the laser at a desired distance to form the plasma filament there. Accordingly, this technique may be used to move the starting point and to extend the length of the plasma filament.

The size, electrical conductivity, and lifetime of the plasma filaments are enhanced by an auxiliary radio-frequency electromagnetic waves or microwaves. The plasma filament may act like an antenna to absorb the auxiliary radio-frequency (RF) electromagnetic waves or microwaves.

The pulsed collection of electric charge and energy is repeated with an optimal (possibly very high) repetition rate of the pulsed laser and of the auxiliary RF waves or microwaves. The energy collected per one pulse should exceed the energy spent on creating and enhancing the plasma filaments, so that the net energy collected is positive. The optimal pulse repetition rate (PRR) depends upon atmospheric conditions which can vary widely over even short time durations. As a general rule, one tries to tune the repetition rate to the plasma relaxation time (the ion-electron recombination time) so that the conductivity of the filament remain as high as is optimal given the atmospheric conditions at the time. A feedback control system that varies the PRR as well as the rest of the pulse-shaping parameters may be employed to optimize the net power production of the system. For more information regarding pulse shaping and tailoring, which is the central theme of the field called "quantum control", please see A. Assion, T. Baumert, M. Bergt, T. Brixner, B. Kiefer, V. Seyfried, M. Strehle, G. Gerber (30 October). "Control of Chemical Reactions by Feedback-Optimized Phase-Shaped Femtosecond Laser Pulses". Science 282 (5390): 919-922. doi: 10.1126/science.282.5390.919. PMID 9794756.

FIG. **2** illustrates a second example of a system **200** for harvesting atmospheric electricity. A plasma filament **120** and a lightning **210** together form a conducting path between ground and a cloud **140**. A condensing mirror **220** directs the beam of laser **110** towards the cloud **140**. A collector **130** is configured to collect electricity flowing along the plasma filament **120**.

In the case of electricity collection from the cloud **140**, the initial and RF-enhanced plasma filaments can be relatively short, not reaching all the way from ground to the cloud **140**. The relatively short plasma filament can be optimized so that it would trigger propagation of the so-called leader (as in natural lightning), which would effectively use the energy and potential of the cloud to eventually create an electrically conducting path between ground and the cloud **140**. The final conducting path would comprise of a plasma filament **120** and a lightning **210**.

It is not shown in the figures, but alternatively both the laser **110** and the collector **130** may be placed on a mobile device, which moves together with the cloud. One such mobile device may be a vehicle moving on the ground, but another such mobile device may be an airplane flying in the air. In the case of an airplane flying in the air, plasma filaments may be formed by the laser to reach both ground and the cloud at the same time. In the event the plasma filament directed at ground is not long enough to reach ground, a lightning may also be formed to complete the conducting path to ground.

FIG. **3**A illustrates a third example of a system **300** for harvesting atmospheric electricity. A laser system situated on an airplane **310** forms two plasma filaments (**321**, **322**) that together complete a conducting path between a first region **331** of a cloud **330** and a second region **332** of the cloud **330**. The first region **331** of the cloud **330** and the second region **332** of the cloud **330** carry opposite electric charges. In the example shown here, the first region **331** of the cloud **330** carries positive electric charges, while the second region **332** of the cloud **330** carries negative electric charges. A collector configured to collect electricity flowing along the two plasma filaments is also situated on the same airplane **310** as the laser. Positive and negative charges are naturally separated within the cloud, so this example makes use of the electrostatic potential gradient between different regions of the same cloud.

FIG. **3**B illustrates a fourth example of the system **300** for harvesting atmospheric electricity. It is similar to FIG. **3**A, except two lightnings (**341**, **342**) complete the conducting path between a first region **331** of a cloud **330** and a second region **332** of the cloud **330** (i.e., a first lightning **341** electrically connects the first region **331** of the cloud **330** to one of the plasma filaments **321** and a second lightning **342** electrically connects the second region **332** of the cloud **330** to the other plasma filaments **322**). The lightning formation is again because the initial and RF-enhanced plasma filaments can be relatively short, not reaching all the way from the collector situated on airplane **310** to the cloud **330**. These relatively short plasma filaments can be optimized so that they would trigger propagation of the so-called leader (as in natural lightning), which would eventually create an electrically conducting path between the two regions of cloud **330** via a connection through airplane **310**. The final conducting path would comprise of two plasma filaments (**321**, **322**) and two lightnings (**341**, **342**). Of course, one of the lightnings may not be formed, if one of the plasma filament can reach all the way from airplane **310** to cloud **330**.

FIG. **4** illustrates a fifth example of the system **300** for harvesting atmospheric electricity. A laser system situated on an airplane **310** forms two plasma filaments (**421**, **431**) that together complete a conducting path between a first cloud **420** and a second cloud **430**. The region **422** of the first cloud **420** that is connected to the first plasma filament **421** and the region **432** of the second cloud **430** that is connected to the second plasma filament **431** carry opposite electric charges. In the example shown here, region **422** of cloud **420** carries positive electric charges, while region **432** of cloud **430** carry negative electric charges. Positive and negative charges are naturally separated within the cloud, so this example makes use of the electrostatic potential gradient between different regions of different clouds. Once again, in case one of the plasma filament cannot reach all the way from airplane **310** to any one of the clouds, then lightning may be formed to complete an electrically conducting path from airplane **310** to any one of the clouds. But these embodiments are not shown in the figures.

FIG. **5** illustrates a sixth example of the system **300** for harvesting atmospheric electricity. A laser system situated on an airplane **310** forms a plasma filament **501** that completes a conducting path between a first region **510** of atmosphere and a second region **520** of atmosphere. A collector situated on the same airplane **310** as the laser system can collect electricity flowing along the plasma filament **501**, because a vertical voltage gradient exists between the first region **510** of atmosphere and the second region **520** of atmosphere. Because no clouds are needed for this embodiment, atmospheric electricity collection is possible under fair weather conditions (relying on the naturally existing vertical voltage gradient in the atmosphere) as well as under foul weather conditions.

FIG. **6** illustrates an example of a collector **130** configured to collect electricity flowing along a plasma filament **620**. The collector may be a charge collection circuit characterized by capacitance **631**, inductance **632**, and resistance **633**. The electricity may be collected by charging a capacitor associated with capacitance **631**. Battery **610** represents these naturally existing voltage sources: (1) between ground and a cloud, (2) between differently charged regions of the same cloud, (3) between differently charged regions of different clouds, and (4) between different regions of atmosphere, where there is a vertical voltage gradient. The plasma filament **620** can, for the purpose of analysis and optimization of the charge collection process, be viewed as electromagnetic transmission lines characterized by their effective capacitance, inductance, and resistance per unit length. Accordingly, the parameters of the charge collection circuit and of the effective transmission line representing the plasma filaments are optimized, so as to maximize the net charge and energy collected (minus the energy spent on generating and enhancing the plasma filaments).

The foregoing description is provided to enable a person skilled in the art to practice the various configurations described herein. While the subject technology has been particularly described with reference to the various figures and configurations, it should be understood that these are for illustration purposes only and should not be taken as limiting the scope of the subject technology.

There may be many other ways to implement the subject technology. Various functions and elements described herein may be partitioned differently from those shown without departing from the scope of the subject technology. Various modifications to these configurations will be readily apparent to those skilled in the art, and generic principles defined herein may be applied to other configurations. Thus, many changes and modifications may be made to the subject technology, by one having ordinary skill in the art, without departing from the scope of the subject technology.

It is understood that the specific order or hierarchy of steps in the processes disclosed is an illustration of exemplary approaches. Based upon design preferences, it is understood that the specific order or hierarchy of steps in the processes may be rearranged. Some of the steps may be performed simultaneously. The accompanying method claims present elements of the various steps in a sample order, and are not meant to be limited to the specific order or hierarchy presented.

A phrase such as “an aspect” does not imply that such aspect is essential to the subject technology or that such aspect applies to all configurations of the subject technology. A disclosure relating to an aspect may apply to all configurations, or one or more configurations. An aspect may provide one or more examples of the disclosure. A phrase such as an "aspect" may refer to one or more aspects and vice versa. A phrase such as an "embodiment" does not imply that such embodiment is essential to the subject technology or that such embodiment applies to all configurations of the subject technology. A disclosure relating to an embodiment may apply to all embodiments, or one or more embodiments. An embodiment may provide one or more examples of the disclosure. A phrase such an "embodiment" may refer to one or more embodiments and vice versa. A phrase such as a "configuration" does not imply that such configuration is essential to the subject technology or that such configuration applies to all configurations of the subject technology. A disclosure relating to a configuration may apply to all configurations, or one or more configurations. A configuration may provide one or more examples of the disclosure. A phrase such as a "configuration" may refer to one or more configurations and vice versa.

Furthermore, to the extent that the term "include," "have," or the like is used in the description or the claims, such term is intended to be inclusive in a manner similar to the term "comprise" as "comprise" is interpreted when employed as a transitional word in a claim.

The word "exemplary" is used herein to mean "serving as an example, instance, or illustration." Any embodiment described herein as "exemplary" is not necessarily to be construed as preferred or advantageous over other embodiments.

A reference to an element in the singular is not intended to mean "one and only one" unless specifically stated, but rather "one or more." The term "some" refers to one or more. Underlined and/or italicized headings and subheadings are used for convenience only, do not limit the subject technology, and are not referred to in connection with the interpretation of the description of the subject technology. All structural and functional equivalents to the elements of the various configurations described throughout this disclosure that are known or later come to be known to those of ordinary skill in the art are expressly incorporated herein by reference and intended to be encompassed by the subject technology. Moreover, nothing disclosed herein is intended to be dedicated to the public regardless of whether such disclosure is explicitly recited in the above description.

What is claimed is the following:

1. A system for harvesting atmospheric electricity, comprising:

a laser configured to form a plasma filament comprising at least a first filament and a second filament, wherein onset of formation of the second filament coincides with an exhaustion range of the first filament;

an auxiliary source of electromagnetic energy operable to enhance the plasma filament by applying electromagnetic energy to the plasma filament; and

a collector configured to collect electricity flowing along the plasma filament.

2. The system of claim **1**, wherein the plasma filament comprises an electrically conducting plasma filament.

3. The system of claim **1**, wherein the laser is a pulsed laser.

4. The system of claim **3**, wherein the pulsed laser is pulsed at an optimal repetition rate.

5. The system of claim **1**, wherein the electromagnetic energy comprises at least one of radio-frequency energy or microwave energy.

6. The system of claim **1**, wherein the plasma filament forms at least a part of a conducting path between ground and a cloud.

7. The system of claim **6**, wherein at least one lightning forms another part of the conducting path between ground and the cloud.

8. The system of claim **1**, wherein the plasma filament forms at least a part of a conducting path between a first region of a cloud and a second region of the cloud.

9. The system of claim **8**, wherein at least one lightning forms another part of the conducting path between the first region of the cloud and the second region of the cloud.

10. The system of claim **1**, wherein:

the laser is further configured to form a second plasma filament,

the plasma filament is connected to a region of a first cloud, and

the second plasma filament is connected to a region of a second cloud.

11. The system of claim **1**, wherein the plasma filament completes a conducting path between a first region of atmosphere and a second region of atmosphere.

12. The system of claim **11**, wherein a vertical voltage gradient exists between the first region of atmosphere and the second region of atmosphere.

13. The system of claim **1**, wherein the collector comprises a charge collection circuit.

14. The system of claim **1**, wherein the laser is situated on ground.

15. The system of claim **1**, wherein the laser is situated on a mobile device.

16. The system of claim **15**, wherein the mobile device is an airplane.

17. The system of claim **1**, wherein negative chirp is used to move the starting point of formation of the plasma filament to a desired location.

18. A method for harvesting atmospheric electricity, the method comprising:

forming a plasma filament with a laser, wherein the plasma filament comprises at least a first filament and a second filament, and wherein onset of formation of the second filament coincides with an exhaustion range of the first filament;

applying electromagnetic energy to the plasma filament to enhance the plasma filament; and

collecting electricity flowing along the plasma filament.

19. An apparatus for harvesting atmospheric electricity, the apparatus comprising:

means for forming a plasma filament with a laser, wherein the plasma filament comprises at least a first filament and a second filament, and wherein onset of formation of the second filament coincides with an exhaustion range of the first filament;

means for applying electromagnetic energy to the plasma filament to enhance the plasma filament; and

means for collecting electricity flowing along the plasma filament.

20. The system of claim **1**, wherein the laser is an ultra short pulse laser (USPL).

21. The system of claim **1**, wherein the laser comprises two coaxial USPL projection optics having different time-lensing parameters.

Fair-weather atmospheric electricity

Basic facts about atmospheric electricity

Atmospheric electricity involves phenomena which are connected with the separation of electric charges in the sub-ionospheric atmosphere (below about 100 km height). In the ionosphere and magnetosphere there occur strong electric currents originating directly from the solar-terrestrial interaction; in the lower atmosphere, there flows a much weaker electric current in the so-called global circuit, which is maintained by the thunderstorm activity. **Charge separation** takes place in three ways:

thermodynamically
In a thundercloud, small ice crystals collide with rime-growing graupels; the crystals gain positive charge, the graupels negative (the microscopic mechanism is not yet well known).
Convection in the thundercloud carries the ice crystals to the cloud top, the heavier graupels staying in the mid-cloud: a macroscopic dipole structure forms.

by radiation ionization
Cosmic and radioactive radiation ionize air, and equal numbers of molecular-size positive and negative small ions are formed; air becomes (weakly) electrically conductive.
Small ions are also attached to airborne dust (aerosol), which thus regularizes the number of small ions.

by collision ionization
Lightning and other discharges in the thundercloud ionize air temporarily into electrically conducting channels.

The mobility of electrically charged particles depends strongly on their size and on the density of the medium. The mobility of small ions in the lower atmosphere corresponds to a (terminal) speed of about 1 cm/s in an electric field of 100 V/m. Dust particles are slower by a few orders of magnitude, so that the electric conductivity of air is practically that due to the small ions. In the stratosphere and mesosphere (10 - 90 km) air becomes thinner and cosmic radiation intensifies so that the conductivity increases exponentially with height: while the electric conductivity of air near the ground is of the order of 20 fS/m (femtosiemens/metre), in the ionosphere it is already as high as that of the ground. (In the ionosphere, the electric conductivity becomes also anisotropic: the geomagnetic field has an increasing influence on the ion motion.)

The thundercloud charge centres, accumulating tens of coulombs of electricity, are discharged mainly by lightning: cloud flashes (most abundant) cause mutual neutralization of the centres; the lower centre is also discharged to the ground - by negative ground flashes - and charges up the earth (the positive centre is discharged similarly, but by a smaller amount). An excess charge will be left in the upper positive centre, and it leaks by conduction to the surrounding air, about one ampere per thunderstrom cell. Because of the exponentially increasing conductivity, most of this leak current is guided to the ionosphere, where it is distributed over the globe and charges the upper atmosphere to a potential of about 300 kV with respect to the ground. This "ionospheric potential" maintains the so-called fair-weather current, whose density is about 2 pA/m^2 (picoamperes per square metre). According to Ohm's law, the fair-weather current density and the electric conductivity are associated with a downward electric field, about 100 V/m near the ground. The number of simultaneously active thunder cells ("thunderstorms") over the globe is about 1000-2000, so the whole circuit carries a current of about 1000 amperes.

About this capture

threat comes from a lightning strike.

The ion balance near the ground can most simply be described by the equation

$q = an^2 + bnN$

where q is ionization, n is the density of small ions (both polarities separately, assumed equal), N is the density of aerosol, and a and b are recombination coefficients, which describe the neutralization of ions with each other or with aerosol particles. a and b are both about 1.6×10^{-12} m^3s^{-1}. Ionization in southern Finland is about 6.6×10^6 $m^{-3}s^{-1}$, one fifth or sixth coming from radioactivity. The small-ion densities are both about 5×10^8 m^{-3} and the aerosol density is more than tenfold, almost 10^{10} m^{-3}.

It should be noted that the notion "dirt increases electric conductivity" is valid for surfaces, for example insulators, but the matter is contrary for air: dirty (dusty) air has poorer conductivity. However, if the "dirt" is a radioactive pollutant, the higher ionization increases the electric conductivity. Such an episode happened in May 1986, when an iodine cloud from the Chernobyl emission arrived at southern Finland: the electric conductivity grew tenfold, but returned to a lower level in a few days, because the half-life of radioactive iodine is 8 days.

Information on international atmospheric electricity research (including lightning research) can be found at the address Atmospheric Electricity HomePage, which among others has a link to a comprehensive English glossary of atmospheric electricity.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

CROSS REFERENCE TO RELATED APPLICATIONS

This application is a continuation in part application of U.S. patent application Ser. No. 12/255,130 filed on Oct. 21, 2008, which is a continuation application of U.S. patent application Ser. No. 11/358,264, filed on Feb. 21, 2006, which are both incorporated by reference herein.

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

FIG. **10** is a system diagram of an exemplary embodiment of a windmill with energy collectors.

DETAILED DESCRIPTION

Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than 100 volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2**A-**2**G using a collection fiber embodiment. FIG. **2**A presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

Likewise, FIG. **2**B shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2**C presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2**D presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2**E provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2**F presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.
